Note: Within nine months from the publication of the mention of the grant of the European patent, any person may give notice to the European Patent Office of opposition to the European patent granted. Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

Description

[0001] This invention relates to ethylene interpolymers and interpolymerization processes. The processes utilize at least one homogeneous polymerization catalyst and at least one heterogeneous polymerization catalyst in separate reactors connected in series or in parallel. Interpolymers produced from such processes are thermoplastic and have surprisingly beneficial properties, including improved impact and tear properties, high modulus and higher crystallization temperatures, and are useful in making molded or shaped articles, and film.

[0002] There are known several polymerization processes for producing polyethylene and ethylene interpolymers, including suspension, gas-phase and solution processes. Of these, the solution process is of commercial significance due to the advantages described in U.S. Pat. 4,330,646 (Sakurai et al.). A most advantageous solution process would be found if the temperature of the polymerization solution could be increased and the properties of the polymers suitably controlled. U.S. Pat. No. 4,314,912 (Lowery et al.) describes a Ziegler-type catalyst suitable for use in high temperature solution polymerization processes. U.S. Pat. No. 4,612,300 (Coleman, III) and USP 4,330,646 describe a catalyst and solution polymerization process for producing polyethylenes having a narrow molecular weight distribution. USP 4,330,646 also describes a process for producing polyethylenes with a broader molecular weight distribution in a solution process. These processes are based on heterogeneous Ziegler type catalysts which produce interpolymers with broad composition distributions regardless of their molecular weight distribution. Such ethylene polymers have deficiencies in some properties, for instance, poor transparency and poor anti-blocking properties.

[0003] WO-A-87/03612 discloses the preparation of interpolymers using transition metal catalysts.

[0004] Solution polymerization processes for producing ethylene interpolymers with narrow composition distributions are also known. U.S. Pat. No. 4,668,752 (Tominari et al.) describes the production of heterogeneous ethylene copolymers with characteristics which include a narrower composition distribution than conventional heterogeneous copolymers. The utility of such polymer compositions in improving mechanical, optical and other important properties of formed or molded objects is also described. The complex structures of the copolymers necessary to achieve such advantages are finely and difficultly controlled by nuances of catalyst composition and preparation; any drift in which would cause a significant loss in the desired properties. U.S. Pat. No. 3,645,992 (Elston) describes the preparation of homogeneous polymers and interpolymers of ethylene in a solution process operated at temperatures of less than 100°C. These polymers exhibit a "narrow composition distribution", a term defined by a comonomer distribution that within a given polymer molecule and between substantially all molecules of the copolymer is the same. The advantages of such copolymers in improving optical and mechanical properties of objects formed from them is described. These copolymers, however, have relatively low melting points and poor thermal resistance.

[0005] U.S. Pat. No. 4,701,432 (Welborn, Jr.) describes a catalyst composition for the production of ethylene polymers having a varied range of composition distributions and/or molecular weight distributions. Such compositions contain a metallocene and a non-metallocene transition metal compound supported catalyst and an aluminoxane. U.S. Pat. No. 4,659,685 (Coleman, III et al.) describes catalysts which are composed of two supported catalysts (one a metallocene complex supported catalyst and the second a non-metallocene transition metal compound supported catalyst) and an aluminoxane. The disadvantages of such catalysts in the commercial manufacture of ethylene polymers are primarily twofold. Although, the choice of the metallocene and a non-metallocene transition metal compounds and their ratio would lead to polymers of controlled molecular structure, the broad range of ethylene polymer structures required to meet all the commercial demands of this polymer family would require a plethora of catalyst compositions and formulations. In particular, the catalyst compositions containing aluminoxanes (which are generally required in high amounts with respect to the transition metal) are unsuitable for higher temperature solution processes as such amount of the aluminum compounds result in low catalyst efficiencies and yield ethylene polymers with low molecular weights and broad molecular weight distributions.

[0006] It would be desirable to provide an economical solution process which would provide ethylene interpolymers with controlled composition and molecular weight distributions. It would be additionally desirable to provide a process for preparing such interpolymers with reduced complexity and greater flexibility in producing a full range of interpolymer compositions in a controllable fashion. It would be particularly desirable to economically produce ethylene interpolymer compositions having improved impact and tear properties, improved optical properties, high modulus and higher thermal stabilities.

[0007] We have now discovered polymerization processes for preparing interpolymer compositions of controlled composition and molecular weight distributions. The processes utilize at least one homogeneous polymerization catalyst and at least one heterogeneous polymerization catalyst in separate reactors connected in series or in parallel.

[0008] In accordance with the invention, there is provided a process for preparing an ethylene/ α -olefin interpolymer composition, characterized by:

(A) reacting by contacting ethylene and at least one other α -olefin under solution polymerization conditions in the presence of a homogeneous catalyst composition in at least one reactor to produce a solution of a first interpolymer

which has a narrow composition distribution, (i.e., one which has a composition distribution branch index (CDBI) of greater than 50 percent where CDBI is defined at the weight percentage of polymer molecules having a comonomer content within 50 percent of the median total comonomer content as measured by the TREF technique defined herein), and a narrow molecular weight distribution (i.e. a molecular weight distribution such that Mw/Mn is less than 3), wherein 15% or less of the first interpolymer has a degree of branching of less than or equal to 2 methyls/1000 carbons and is lacking a measurable homopolymer fraction as measured by the TREF technique, and wherein the homogeneous catalyst composition contains either no aluminum cocatalyst or contains an amount of aluminum cocatalyst which will give rise to a detectable aluminum residue in the product of less than or equal to 250 ppm,

(B) reacting by contacting ethylene and at least one other α -olefin under solution polymerization conditions and at a higher polymerization reaction temperature than used in step (A) in the presence of a heterogeneous Ziegler catalyst in at least one other reactor to produce a solution of a second interpolymer which has a broad composition distribution (i.e. a composition distribution such that the composition has a homopolymer fraction as measured by the TREF technique and has multiple melting peaks), and a broad molecular weight distribution (i.e. a molecular weight distribution such that Mw/Mn is greater than 3), wherein 10 weight percent or more of the second interpolymer has a degree of branching of less than 2 methyls/1000 carbons, and wherein 25 weight percent or less of the second interpolymer has a degree of branching of 25 methyls/1000 carbons or more, wherein the Ziegler catalyst comprises.

- (i) a solid support component derived from a magnesium halide or silica, and
- (ii) a transition metal component represented by the formula: $\text{TrX}'_4\text{-q}(\text{OR}1)_q$, $\text{TrX}'_4\text{-q}(\text{R}2)_q$, VOX'_3 or $\text{VO}(\text{OR}1)_3$, wherein:

Tr is a Group, IVB, VB, or VIB metal,

q is 0 or a number equal to or less than 4,

X' is a halogen, and

R1 is an alkyl group, aryl group or cycloalkyl group having from 1 to 20 carbon atoms, and

R2 is an alkyl group, aryl group, aralkyl group, or substituted aralkyl group, and

(C) combining the solution of the first interpolymer with the solution of the second interpolymer to form a polymer solution comprising the ethylene- α -olefin interpolymer composition, and

(D) removing the solvent from the polymer solution of step (C) and recovering the ethylene- α -olefin interpolymer composition.

[0009] These polymerizations are generally carried out under solution conditions to facilitate the intimate mixing of the two polymer-containing streams. The homogeneous catalyst is chosen from those metallocene-type catalysts which are capable of producing ethylene/ α -olefin interpolymers of sufficiently high molecular weight under solution process polymerization conditions (e.g., temperatures greater than or equal to about 100°C). The heterogeneous catalyst is also chosen from those catalysts which are capable of efficiently producing the polymers under high temperature (e.g., temperatures greater than or equal to about 180°C) solution process conditions.

[0010] In a second aspect of the invention, there is provided a process for preparing an ethylene/ α -olefin interpolymer composition, characterized by:

(A) polymerizing ethylene and at least one other α -olefin under solution polymerization conditions in at least one reactor containing a homogeneous catalyst composition to produce a solution of a first interpolymer which has a narrow composition distribution, (i.e., one which has a composition distribution branch index (CDBI) of greater than 50 percent where CDBI is defined at the weight percentage of polymer molecules having a comonomer content within 50 percent of the median total comonomer content as measured by the TREF technique defined herein), and a narrow molecular weight distribution (i.e. a molecular weight distribution such that Mw/Mn is less than 3), wherein 15% or less of the first interpolymer has a degree of branching of less than or equal to 2 methyls/1000 carbons and is lacking a measurable homopolymer fraction as measured by the TREF technique, and wherein the homogeneous catalyst composition contains either no aluminum cocatalyst or contains an amount of aluminum cocatalyst which will give rise to a detectable aluminum residue in the product of less than or equal to 250 ppm,

(B) sequentially passing the interpolymer solution of (A) into at least one other reactor containing a heterogeneous Ziegler catalyst, ethylene and at least one other α -olefin, under solution polymerization conditions and at a higher polymerization reaction temperature than used in step (A) to produce a solution comprising the ethylene/ α -olefin interpolymer composition, wherein the Ziegler catalyst comprises

- (i) a solid support component derived from a magnesium halide or silica, and
- (ii) a transition metal component represented by the formula: $\text{TrX}'_4\text{-q(OR1)q}$, $\text{TrX}'_4\text{-q(R2)q}$, VOX'_3 or VO(OR1)_3 , wherein:

Tr is a Group, IVB, VB, or VIB metal,
 q is 0 or a number equal to or less than 4,
 X' is a halogen, and
 R1 is an alkyl group, aryl group or cycloalkyl group having from 1 to 20 carbon atoms, and
 R2 is an alkyl group, aryl group, aralkyl group, or substituted aralkyl group, and

(C) combining the solution of the first interpolymers with the solution of the second interpolymers to form a polymer solution comprising the ethylene- α -olefin interpolymers composition, and

(D) removing the solvent from the polymer solution of step (C) and recovering the ethylene- α -olefin interpolymers composition.

[0011] In either process, the homogeneous catalyst composition preferably exhibits a high reactivity ratio and very readily incorporates higher α -olefins.

[0012] The homogeneous catalysts employed in the production of the homogeneous ethylene interpolymers are desirably derived from monocyclopentadienyl complexes of the Group IV transition metals which contain a pendant bridging group attached to the cyclopentadienyl ring which acts as a bident ligand. Complex derivatives of titanium in the +3 or +4 oxidation state are preferred.

[0013] In another aspect of this invention, there are provided novel interpolymers of ethylene and at least one α -olefin, wherein the interpolymers have controlled composition and molecular weight distributions. The interpolymers have improved mechanical, thermal and optical properties and, surprisingly, the polymer compositions obtained by the processes described herein provide superior properties to materials obtained by merely blending the solid polymers obtained from process step (A) or (B) individually, in the First Process listed above.

[0014] The novel polymer compositions of the present invention can be ethylene homopolymers or, preferably, interpolymers of ethylene with at least one $\text{C}_3\text{-C}_{20}$ α -olefin and/or $\text{C}_4\text{-C}_{18}$ diolefins. Interpolymers of ethylene and 1-octene are especially preferred. The term "interpolymer" is used herein to indicate a copolymer, or a terpolymer, or the like. That is, at least one other comonomer is polymerized with ethylene to make the interpolymer.

Detailed Description of the Invention

[0015] The homogeneous interpolymers used in the present invention are herein defined as defined in USP 3,645,992 (Elston). Accordingly, homogeneous polymers and interpolymers are those in which the comonomer is randomly distributed within a given interpolymer molecule and wherein substantially all of the interpolymer molecules have the same ethylene/comonomer ratio within that interpolymer, whereas heterogeneous interpolymers are those in which the interpolymer molecules do not have the same ethylene/comonomer ratio.

[0016] The term "narrow composition distribution" used herein describes the comonomer distribution for homogeneous interpolymers and means that the homogeneous interpolymers have only a single melting peak and essentially lack a measurable "linear" polymer fraction. The narrow composition distribution homogeneous interpolymers can also be characterized by their SCBDI (Short Chain Branch Distribution Index) or CDBI (Composition Distribution Branch Index). The SCBDI or CDBI is defined as the weight percent of the polymer molecules having a comonomer content within 50 percent of the median total molar comonomer content. The CDBI of a polymer is readily calculated from data obtained from techniques known in the art, such as, for example, temperature rising elution fractionation (abbreviated herein as "TREF") as described, for example, in Wild et al, *Journal of Polymer Science, Poly. Phys. Ed.*, Vol. 20, p. 441 (1982), or in U.S. Patent 4,798,081. The SCBDI or CDBI for the narrow composition distribution homogeneous interpolymers and copolymers of the present invention is preferably greater than 30 percent, especially greater than 50 percent. The narrow composition distribution homogeneous interpolymers and copolymers used in this invention essentially lack a measurable "high density" (i.e., "linear" or homopolymer) fraction as measured by the TREF technique. The homogeneous interpolymers have a degree of branching less than or equal to 2 methyls/1000 carbons in 15 percent (by weight) or less preferably less than 10 percent (by weight), and especially less than 5 percent (by weight).

[0017] The term "broad composition distribution" used herein describes the comonomer distribution for heterogeneous interpolymers and means that the heterogeneous interpolymers have a "linear" fraction and that the heterogeneous interpolymers have multiple melting peaks (i.e., exhibit at least two distinct melting peaks). The heterogeneous interpolymers and polymers have a degree of branching less than or equal to 2 methyls/1000 carbons in 10 percent (by weight) or more, preferably more than 15 percent (by weight), and especially more than 20 percent (by weight). The heterogeneous interpolymers also have a degree of branching equal to or greater than 25 methyls/1000 carbons in 25 percent

cent or less (by weight), preferably less than 15 percent (by weight), and especially less than 10 percent (by weight).

[0018] The homogeneous interpolymers used to make the novel polymer compositions of the present invention are preferably interpolymers of ethylene with at least one C_3 - C_{20} α -olefin and/or C_4 - C_{18} diolefins. Homogeneous copolymers of ethylene and propylene, butene-1, hexene-1, 4-methyl-1-pentene and octene-1 are preferred and copolymers of ethylene and 1-octene are especially preferred.

[0019] The homogenous ethylene interpolymer and the heterogeneous ethylene interpolymer used in the compositions described herein can each be made separately in different reactors, and subsequently blended together to make the interpolymer compositions of the present invention. Preferably, though, the homogeneous ethylene polymer and the heterogeneous ethylene polymer used in the compositions described herein are made in a multiple reactor scheme, operated either in parallel or in series. In the multiple reactor scheme, at least one of the reactors makes the homogeneous ethylene interpolymer and at least one of the reactors makes the heterogeneous ethylene interpolymer. In a preferred mode of operation, the reactors are operated in a series configuration to make most advantage of the high polymerization temperatures allowed by the heterogeneous catalyst. When the reactors are connected in series, the polymerization reaction product from step (A) is fed directly (i.e., sequentially) into the reactor(s) for step (B) along with the ethylene/ α -olefin reactants and heterogeneous catalyst and solvent.

[0020] Other unsaturated monomers usefully polymerized according to the present invention include, for example, ethylenically unsaturated monomers, conjugated or nonconjugated dienes, polyenes, etc. Preferred monomers include the C_2 - C_{10} α -olefins especially ethylene, 1-propene, 1-butene, 1-hexene, 4-methyl-1-pentene, and 1-octene. Other preferred monomers include styrene, halo- or alkyl substituted styrenes, vinylbenzocyclobutane, 1,4-hexadiene, cyclopentene, cyclohexene and cyclooctene.

[0021] The density of the ethylene interpolymer compositions of the present invention is measured in accordance with ASTM D-792 and is generally from 0.87 g/cm³ to 0.965 g/cm³, preferably from 0.88 g/cm³ to 0.95 g/cm³, and especially from 0.9 g/cm³ to 0.935 g/cm³. The density of the homogeneous ethylene polymer used to make the ethylene polymer compositions is generally from 0.865 g/cm³ to 0.92 g/cm³, preferably from 0.88 g/cm³ to 0.915 g/cm³, and especially from 0.89 g/cm³ to 0.91 g/cm³. The density of the heterogeneous ethylene polymer used to make the ethylene polymer compositions is generally from 0.9 g/cm³ to 0.965 g/cm³, preferably from 0.9 g/cm³ to 0.95 g/cm³, and especially from 0.915 g/cm³ to 0.935 g/cm³.

[0022] Generally, the amount of the ethylene interpolymer produced using the homogeneous catalyst and incorporated into the ethylene interpolymer composition is from 15 percent to 85 percent, by weight of the composition, preferably 25 percent to 75 percent, by weight of the composition.

[0023] The molecular weight of the ethylene interpolymer compositions for use in the present invention is conveniently indicated using a melt index measurement according to ASTM D-1238, condition 190 C/2.16 kg (formally known as "Condition (E)" and also known as I_2). Melt index is inversely proportional to the molecular weight of the polymer. Thus, the higher the molecular weight, the lower the melt index, although the relationship is not linear. The melt index for the ethylene interpolymer compositions used herein is generally from 0.1 grams/10 minutes (g/10 min) to 100 g/10 min, preferably from 0.3 g/10 min to 30 g/10 min, and especially from 0.5 g/10 min to 10 g/10 min.

[0024] Additives such as antioxidants (e.g., hindered phenolics (e.g., Irganox[®] 1010 made by Ciba Geigy Corp.), phosphites (e.g., Irgafos[®] 168 also made by Ciba Geigy Corp.)), cling additives (e.g., polyisobutylene (PIB)), antiblock additives, pigments, and the like can also be included in the polyethylene compositions, to the extent that they do not interfere with the enhanced composition properties discovered by Applicants.

The Homogeneous Catalysts

[0025] The homogeneous catalysts used in the invention are based on those monocyclopentadienyl transition metal complexes described in the art as constrained geometry metal complexes. These catalysts are highly efficient, meaning that they are efficient enough such that the catalyst residues left in the polymer do not influence the polymer quality. Typically, less than or equal to 10 ppm of the metal atom (designated herein as "M") is detectable and, when using the appropriate cocatalyst (e.g., one of the aluminoxanes described herein) the detectable aluminum residue is less than or equal to 250 ppm. Suitable constrained geometry catalysts for use herein preferably include constrained geometry catalysts as disclosed in European patent publication 416,815. The monocyclopentadienyl transition metal olefin polymerization catalysts taught in USP 5,026,798 (Canich) are also suitable for use in preparing the polymers of the present invention.

[0026] The foregoing catalysts may be further described as comprising a metal coordination complex comprising a metal of group 4 of the Periodic Table of the Elements and a delocalized π -bonded moiety substituted with a constrain-inducing moiety, said complex having a constrained geometry about the metal atom such that the angle at the metal between the centroid of the delocalized, substituted π -bonded moiety and the center of at least one remaining substituent is less than such angle in a similar complex containing a similar π -bonded moiety lacking in such constrain-inducing substituent, and provided further that for such complexes comprising more than one delocalized, substituted π -

bonded moiety, only one thereof for each metal atom of the complex is a cyclic, delocalized, substituted π -bonded moiety. The catalyst further comprises an activating cocatalyst.

[0027] Preferred catalyst complexes correspond to the formula:

15 wherein:

M is a metal of group 4 of the Periodic Table of the Elements;

Cp* is a cyclopentadienyl or substituted cyclopentadienyl group bound in an h^5 bonding mode to M;

Z is a moiety comprising boron, or a member of group 14 of the Periodic Table of the Elements, and optionally sulfur or oxygen, said moiety having up to 20 non-hydrogen atoms, and optionally Cp* and Z together form a fused ring system;

X independently each occurrence is an anionic ligand group having up to 30 non-hydrogen atoms;

n is 1 or 2; and

Y is an anionic or nonanionic ligand group bonded to Z and M comprising nitrogen, phosphorus, oxygen or sulfur and having up to 20 non-hydrogen atoms, optionally Y and Z together form a fused ring system.

[0028] More preferably still, such complexes correspond to the formula:

wherein:

R' each occurrence is independently selected from the group consisting of hydrogen, alkyl, aryl, and silyl, and combinations thereof having up to 20 non-hydrogen atoms;

X each occurrence independently is selected from the group consisting of hydride, halo, alkyl, aryl, silyl, aryloxy, alkoxy, amide, siloxy and combinations thereof having up to 20 non-hydrogen atoms;

Y is -O-, -S-, -NR⁺-, -PR⁺-, or a neutral two electron donor ligand selected from the group consisting of OR⁺, SR⁺, NR⁺₂ or PR⁺₂;

M is as previously defined; and

Z is SiR^*_2 , CR^*_2 , $\text{SiR}^*_2\text{SiR}^*_2$, $\text{CR}^*_2\text{CR}^*_2$, $\text{CR}^*=\text{CR}^*$, $\text{CR}^*_2\text{SiR}^*_2$, BR^* ; wherein

- 5 R^* each occurrence is independently selected from the group consisting of hydrogen, alkyl, aryl, silyl groups having up to 20 non-hydrogen atoms, and mixtures thereof, or two or more R^* groups from Y, Z, or both Y and Z form a fused ring system; and n is 1 or 2.

10 **[0029]** Most highly preferred complex compounds are amidosilane- or amidoalkanedyl- compounds corresponding to the formula:

25 wherein:

M is titanium, zirconium or hafnium, bound in an h^5 bonding mode to the cyclopentadienyl group;

30 R' each occurrence is independently selected from the group consisting of hydrogen, alkyl and aryl and combinations thereof having up to 7 carbon atoms, or silyl;

E is silicon or carbon;

35 X independently each occurrence is hydride, halo, alkyl, aryl, aryloxy or alkoxy of up to 10 carbons, or silyl;

m is 1 or 2; and

n is 1 or 2.

40 **[0030]** Examples of the above most highly preferred metal coordination compounds include compounds wherein the R' on the amido group is methyl, ethyl, propyl, butyl, pentyl, hexyl, (including isomers), norbornyl, benzyl, phenyl, etc.; the cyclopentadienyl group is cyclopentadienyl, indenyl, tetrahydroindenyl, fluorenyl, octahydrofluorenyl, etc.; R' on the foregoing cyclopentadienyl groups each occurrence is hydrogen, methyl, ethyl, propyl, butyl, pentyl, hexyl, (including isomers), norbornyl, benzyl, phenyl, etc.; and X is chloro, bromo, iodo, methyl, ethyl, propyl, butyl, pentyl, hexyl, (including isomers), norbornyl, benzyl, phenyl, etc.

45 **[0031]** Specific compounds include; (tert-butylamido)(tetramethyl- h^5 -cyclopentadienyl)-1,2-ethanedylzirconium dichloride, (tert-butylamido)(tetramethyl- h^5 -cyclopentadienyl)-1,2-ethanedyltitanium dichloride, (methylamido)(tetramethyl- h^5 -cyclopentadienyl)-1,2-ethanedylzirconium dichloride, (methylamido)(tetramethyl- h^5 -cyclopentadienyl)-1,2-ethanedyltitanium dichloride, (ethylamido)(tetramethyl- h^5 -cyclopentadienyl)methylenetitanium dichloride, (tert-butylamido)dibenzyl(tetramethyl- h^5 -cyclopentadienyl) silanezirconium dibenzyl, (benzylamido)dimethyl- (tetramethyl- h^5 -cyclopentadienyl)silanetitanium dichloride, (phenylphosphido)dimethyl(tetramethyl- h^5 -cyclopentadienyl)silanezirconium dibenzyl, (tert-butylamido)dimethyl(tetramethyl- h^5 -cyclopentadienyl)silanetitanium dimethyl, and the like.

50 **[0032]** The catalyst compositions are derived from reacting the metal complex compounds with a suitable activating agent or cocatalyst or combination of cocatalysts. Suitable cocatalysts for use herein include polymeric or oligomeric aluminoxanes, especially aluminoxanes soluble in non-aromatic hydrocarbon solvent, as well as inert, compatible, non-coordinating, ion forming compounds; or combinations of polymeric/oligomeric aluminoxanes and inert, compatible, noncoordinating, ion forming compounds. Preferred cocatalysts contain inert, noncoordinating, boron compounds.

[0033] Ionic active catalyst species which can be used to polymerize the polymers described herein correspond to

the formula:

wherein:

M is a metal of group 4 of the Periodic Table of the Elements;

Cp* is a cyclopentadienyl or substituted cyclopentadienyl group bound in an η^5 bonding mode to M;

Z is a moiety comprising boron, or a member of group 14 of the Periodic Table of the Elements, and optionally sulfur or oxygen, said moiety having up to 20 non-hydrogen atoms, and optionally Cp* and Z together form a fused ring system;

X independently each occurrence is an anionic ligand group having up to 30 non-hydrogen atoms;

n is 1 or 2; and

A- is a noncoordinating, compatible anion.

[0034] One method of making the ionic catalyst species which can be utilized to make the polymers of the present invention involve combining:

- a) at least one first component which is a mono(cyclopentadienyl) derivative of a metal of Group 4 of the Periodic Table of the Elements as described previously containing at least one substituent which will combine with the cation of a second component (described hereinafter) which first component is capable of forming a cation formally having a coordination number that is one less than its valence, and
- b) at least one second component which is a salt of a Bronsted acid and a noncoordinating, compatible anion.

[0035] Compounds useful as a second component in the preparation of the ionic catalysts useful in this invention can comprise a cation, which is a Bronsted acid capable of donating a proton, and a compatible noncoordinating anion. Preferred anions are those containing a single coordination complex comprising a charge-bearing metal or metalloid core which anion is relatively large (bulky), capable of stabilizing the active catalyst species (the Group 4 cation) which is formed when the two components are combined and sufficiently labile to be displaced by olefinic, diolefinic and acetylenically unsaturated substrates or other neutral Lewis bases such as ethers, nitriles and the like. Compounds containing anions which comprise coordination complexes containing a single metal or metalloid atom are, of course, well known and many, particularly such compounds containing a single boron atom in the anion portion, are available commercially. In light of this, salts containing anions comprising a coordination complex containing a single boron atom are preferred.

[0036] Highly preferably, the second component useful in the preparation of the catalysts of this invention may be represented by the following general formula:

wherein:

L is a neutral Lewis base ;

(L-H)⁺ is a Bronsted acid; and

[A]⁻ is a compatible, noncoordinating anion.

[0037] More preferably [A]⁻ corresponds to the formula:

wherein:

B is boron in a valence state of 3; and

Q independently each occurrence is selected from the Group consisting of hydride, dialkylamido, halide, alkoxide, aryloxy, hydrocarbyl, and substituted-hydrocarbyl radicals of up to 20 carbons with the proviso that in not more than one occurrence is Q halide.

[0038] Illustrative, but not limiting, examples of boron compounds which may be used as a second component in the preparation of the improved catalysts of this invention are trialkyl-substituted ammonium salts such as triethylammonium tetraphenylborate, tripropylammonium tetraphenylborate, tris(n-butyl)ammonium tetraphenylborate, trimethylammonium tetrakis(p-tolyl)borate, tributylammonium tetrakis(pentafluorophenyl)borate, tripropylammonium tetrakis(2,4-dimethylphenyl)borate, tributylammonium tetrakis(3,5-dimethylphenyl)borate, triethylammonium tetrakis(3,5-di-trifluoromethylphenyl)borate and the like. Also suitable are N,N-dialkylanilinium salts such as N,N-dimethylanilinium tetraphenylborate, N,N-diethylanilinium tetraphenylborate, N,N,2,4,6-pentamethylanilinium tetraphenylborate and the like; dialkylammonium salts such as di(i-propyl)ammonium tetrakis(pentafluorophenyl)borate, dicyclohexylammonium tetraphenylborate and the like; and triarylphosphonium salts such as triphenylphosphonium tetraphenylborate, tris(methylphenyl)phosphonium tetrakis(pentafluorophenyl)borate, tris(dimethylphenyl)phosphonium tetraphenylborate and the like.

[0039] Preferred ionic catalysts are those having a limiting charge separated structure corresponding to the formula:

wherein:

M is a metal of group 4 of the Periodic Table of the Elements;

Cp⁺ is a cyclopentadienyl or substituted cyclopentadienyl group bound in an h⁵ bonding mode to M;

Z is a moiety comprising boron, or a member of group 14 of the Periodic Table of the Elements, and optionally sulfur or oxygen, said moiety having up to 20 non-hydrogen atoms, and optionally Cp⁺ and Z together form a fused ring system;

X independently each occurrence is an anionic ligand group having up to 30 non-hydrogen atoms;

n is 1 or 2; and

XA^{*-} is X(B(C₆F₅)₃).

[0040] This class of cationic complexes can also be conveniently prepared by contacting a metal compound corresponding to the formula:

wherein:

Cp*, M, and n are as previously defined,
with tris(pentafluorophenyl)borane cocatalyst under conditions to cause abstraction of X and formation of the anion $X(B(C_6F_5)_3)$.

[0041] Preferably X in the foregoing ionic catalyst is C₁-C₁₀ hydrocarbyl, most preferably methyl or benzyl.

[0042] The preceding formula is referred to as the limiting, charge separated structure. However, it is to be understood that, particularly in solid form, the catalyst may not be fully charge separated. That is, the X group may retain a partial covalent bond to the metal atom, M. Thus, the catalysts may be alternately depicted as possessing the formula:

[0043] The catalysts are preferably prepared by contacting the derivative of a Group 4 metal with the tris(pentafluorophenyl)borane in an inert diluent such as an organic liquid. Tris(pentafluorophenyl)borane is a commonly available Lewis acid that may be readily prepared according to known techniques. The compound is disclosed in Marks, et al. *J. Am. Chem. Soc.* 1991, 113, 3623-3625 for use in alkyl abstraction of zirconocenes.

[0044] The homogeneous catalyst can contain either no aluminum cocatalyst or only a small amount (i.e., from 3:1 Al:M ratio to 100:1 Al:M ratio) of aluminum cocatalyst. For example, the cationic complexes used as homogeneous catalysts may be further activated by the use of an additional activator such as an alkylaluminumoxane. Preferred co-activators include methylaluminumoxane, propylaluminumoxane, isobutylaluminumoxane, combinations thereof and the like. So-called modified methylaluminumoxane (MMAO) is also suitable for use as a cocatalyst. One technique for preparing such modified aluminumoxane is disclosed in U.S. Patent 4,960,878 (Crapo et al.). Aluminumoxanes can also be made as disclosed in U.S. Patents Nos. 4,544,762 (Kaminsky et al.); 5,015,749 (Schmidt et al.); 5,041,583 (Sangokoya); 5,041,584 (Crapo et al.); and 5,041,585 (Deavenport et al.).

[0045] The homogeneous catalysts useful for the production of the ethylene interpolymers of narrow composition and molecular weight distribution may also be supported on an inert support. Typically, the support can be any solid, particularly porous supports such as talc or inorganic oxides, or resinous support materials such as a polyolefin. Preferably, the support material is an inorganic oxide in finely divided form.

[0046] Suitable inorganic oxide materials which are desirably employed in accordance with this invention include Group IIA, IIIA, IVA, or IVB metal oxides such as silica, alumina, and silica-alumina and mixtures thereof. Other inorganic oxides that may be employed either alone or in combination with the silica, alumina or silica-alumina are magnesia, titania, zirconia, and the like. Other suitable support materials, however, can be employed, for example, finely divided polyolefins such as finely divided polyethylene.

[0047] The metal oxides generally contain acidic surface hydroxyl groups which will react with the homogeneous catalyst component added to the reaction slurry. Prior to use, the inorganic oxide support is dehydrated, i.e., subjected

to a thermal treatment in order to remove water and reduce the concentration of the surface hydroxyl groups. The treatment is carried out in vacuum or while purging with a dry inert gas such as nitrogen at a temperature of 100°C to 1000°C, and preferably, from 300°C to 800°C. Pressure considerations are not critical. The duration of the thermal treatment can be from 1 to 24 hours; however, shorter or longer times can be employed provided equilibrium is established with the surface hydroxyl groups.

The Heterogeneous Catalysts

[0048] The heterogeneous catalysts suitable for use in the invention are typical supported, Ziegler-type catalysts which are particularly useful at the high polymerization temperatures of the solution process. Examples of such compositions are those derived from organomagnesium compounds, alkyl halides or aluminum halides or hydrogen chloride, and a transition metal compound. Examples of such catalysts are described in U.S. Pat Nos. 4,314,912 (Lowery, Jr. et al.), 4,547,475 (Glass et al.), and 4,612,300 (Coleman, III).

[0049] Particularly suitable organomagnesium compounds include, for example, hydrocarbon soluble dihydrocarbylmagnesium such as the magnesium dialkyls and the magnesium diaryls. Exemplary suitable magnesium dialkyls include particularly n-butyl-sec-butylmagnesium, diisopropylmagnesium, di-n-hexylmagnesium, isopropyl-n-butylmagnesium, ethyl-n-hexylmagnesium, ethyl-n-butylmagnesium, di-n-octylmagnesium and others wherein the alkyl has from 1 to 20 carbon atoms. Exemplary suitable magnesium diaryls include diphenylmagnesium, dibenzylmagnesium and ditolylmagnesium. Suitable organomagnesium compounds include alkyl and aryl magnesium alkoxides and aryloxides and aryl and alkyl magnesium halides with the halogen-free organomagnesium compounds being more desirable.

[0050] Among the halide sources which can be employed herein are the active non-metallic halides, metallic halides, and hydrogen chloride.

[0051] Suitable non-metallic halides are represented by the formula R^*X wherein R^* is hydrogen or an active monovalent organic radical and X is a halogen. Particularly suitable non-metallic halides include, for example, hydrogen halides and active organic halides such as t-alkyl halides, allyl halides, benzyl halides and other active hydrocarbyl halides wherein hydrocarbyl is as defined hereinbefore. By an active organic halide is meant a hydrocarbyl halide that contains a labile halogen at least as active, i.e., as easily lost to another compound, as the halogen of sec-butyl chloride, preferably as active as t-butyl chloride. In addition to the organic monohalides, it is understood that organic dihalides, trihalides and other polyhalides that are active as defined hereinbefore are also suitably employed. Examples of preferred active non-metallic halides include hydrogen chloride, hydrogen bromide, t-butyl chloride, t-amyl bromide, allyl chloride, benzyl chloride, crotyl chloride, methylvinyl carbonyl chloride, α -phenylethyl bromide, diphenyl methyl chloride and the like. Most preferred are hydrogen chloride, t-butyl chloride, allyl chloride and benzyl chloride.

[0052] Suitable metallic halides which can be employed herein include those represented by the formula $MR_{y-a}X_a$ wherein:

M is a metal of Groups IIB, IIIA or IVA of Mendeleev's Periodic Table of Elements,

R is a monovalent organic radical,

X is a halogen,

Y has a value corresponding to the valence of M, and

a has a value from 1 to y.

[0053] Preferred metallic halides are aluminum halides of the formula $AlR_{3-a}X_a$ wherein:

each R is independently hydrocarbyl as hereinbefore defined such as alkyl,

X is a halogen and

a is a number from 1 to 3.

[0054] Most preferred are alkylaluminum halides such as ethylaluminum sesquichloride, diethylaluminum chloride, ethylaluminum dichloride, and diethylaluminum bromide, with ethylaluminum dichloride being especially preferred. Alternatively, a metal halide such as aluminum trichloride or a combination of aluminum trichloride with an alkyl aluminum halide or a trialkyl aluminum compound may be suitably employed.

[0055] It is understood that the organic moieties of the aforementioned organomagnesium, e.g., R^* , and the organic moieties of the halide source, e.g., R and R' , are suitably any other organic radical provided that they do not contain functional groups that poison conventional Ziegler catalysts.

[0056] The magnesium halide can be preformed from the organomagnesium compound and the halide source or it can be formed in situ in which instance the catalyst is preferably prepared by mixing in a suitable solvent or reaction medium (1) the organomagnesium component and (2) the halide source, followed by the other catalyst components.

[0057] Any of the conventional Ziegler-Natta transition metal compounds can be usefully employed as the transition

metal component in preparing the supported catalyst component. Typically, the transition metal component is a compound of a Group IVB, VB, or VIB metal. The transition metal component is generally represented by the formulas: $\text{TrX}'_{4-q}(\text{OR}^1)_q$, $\text{TrX}'_{4-q}\text{R}^2_q$, VOX'_3 and $\text{VO}(\text{OR}^1)_3$.

- 5 Tr is a Group IVB, VB, or VIB metal, preferably a Group IVB or VB metal, preferably titanium, vanadium or zirconium,
 q is 0 or a number equal to or less than 4,
 X' is a halogen, and
 R¹ is an alkyl group, aryl group or cycloalkyl group having from 1 to 20 carbon atoms, and
 10 R² is an alkyl group, aryl group, aralkyl group, substituted aralkyls, and the like. The aryl, aralkyls and substituted aralkyls contain 1 to 20 carbon atoms, preferably 1 to 10 carbon atoms. When the transition metal compound contains a hydrocarbyl group, R², being an alkyl, cycloalkyl, aryl, or aralkyl group, the hydrocarbyl group will preferably not contain an H atom in the position beta to the metal carbon bond. Illustrative but non-limiting examples of aralkyl groups are methyl, neo-pentyl, 2,2-dimethylbutyl, 2,2-dimethylhexyl; aryl groups such as benzyl; cycloalkyl groups
 15 such as 1-norbornyl. Mixtures of these transition metal compounds can be employed if desired.

[0058] Illustrative examples of the transition metal compounds include TiCl_4 , TiBr_4 , $\text{Ti}(\text{OC}_2\text{H}_5)_3\text{Cl}$, $\text{Ti}(\text{OC}_2\text{H}_5)\text{Cl}_3$, $\text{Ti}(\text{OC}_4\text{H}_9)_3\text{Cl}$, $\text{Ti}(\text{OC}_3\text{H}_7)_2\text{Cl}_2$, $\text{Ti}(\text{OC}_6\text{H}_{13})_2\text{Cl}_2$, $\text{Ti}(\text{OC}_8\text{H}_{17})_2\text{Br}_2$, and $\text{Ti}(\text{OC}_{12}\text{H}_{25})\text{Cl}_3$, $\text{Ti}(\text{O}-i\text{-C}_3\text{H}_7)_4$, and $\text{Ti}(\text{O}-n\text{-C}_4\text{H}_9)_4$.

20 [0059] Illustrative examples of vanadium compounds include VCl_4 , VOCl_3 , $\text{VO}(\text{OC}_2\text{H}_5)_3$, and $\text{VO}(\text{OC}_4\text{H}_9)_3$.

[0060] Illustrative examples of zirconium compounds include ZrCl_4 , $\text{ZrCl}_3(\text{OC}_2\text{H}_5)$, $\text{ZrCl}_2(\text{OC}_2\text{H}_5)_2$, $\text{ZrCl}(\text{OC}_2\text{H}_5)_3$, $\text{Zr}(\text{OC}_2\text{H}_5)_4$, $\text{ZrCl}_3(\text{OC}_4\text{H}_9)$, $\text{ZrCl}_2(\text{OC}_4\text{H}_9)_2$, and $\text{ZrCl}(\text{OC}_4\text{H}_9)_3$.

[0061] As indicated above, mixtures of the transition metal compounds may be usefully employed, no restriction being imposed on the number of transition metal compounds which may be contracted with the support. Any halogenide and alkoxide transition metal compound or mixtures thereof can be usefully employed. The previously named transition metal compounds are especially preferred with vanadium tetrachloride, vanadium oxychloride, titanium tetraisopropoxide, titanium tetrabutoxide, and titanium tetrachloride being most preferred.

[0062] Suitable catalyst materials may also be derived from a inert oxide supports and transition metal compounds. Examples of such compositions suitable for use in the solution polymerization process are described in U. S. Patent No. 5,231,151.

30 [0063] The inorganic oxide support used in the preparation of the catalyst may be any particulate oxide or mixed oxide as previously described which has been thermally or chemically dehydrated such that it is substantially free of adsorbed moisture.

[0064] The specific particle size, surface area, pore volume, and number of surface hydroxyl groups characteristic of the inorganic oxide are not critical to its utility in the practice of the invention. However, since such characteristics determine the amount of inorganic oxide to be employed in preparing the catalyst compositions, as well as affecting the properties of polymers formed with the aid of the catalyst compositions, these characteristics must frequently be taken into consideration in choosing an inorganic oxide for use in a particular aspect of the invention. In general, optimum results are usually obtained by the use of inorganic oxides having an average particle size in the range of 1 to 100
 40 microns, preferably 2 to 20 microns; a surface area of 50 to 1,000 square meters per gram, preferably 100 to 400 square meters per gram; and a pore volume of 0.5 to 3.5 cm^3 per gram; preferably 0.5 to 2 cm^3 per gram.

[0065] In order to further improve catalyst performance, surface modification of the support material may be desired. Surface modification is accomplished by specifically treating the support material such as silica, alumina or silica-alumina with an organometallic compound having hydrolytic character. More particularly, the surface modifying agents for the support materials comprise the organometallic compounds of the metals of Group IIA and IIIA of the Periodic Table. Most preferably the organometallic compounds are selected from magnesium and aluminum organometallics and especially from magnesium and aluminum alkyls or mixtures thereof represented by the formulas and R^1MgR^2 and $\text{R}^1\text{R}^2\text{AlR}^3$ wherein each of R¹, R² and R³ which may be the same or different are alkyl groups, aryl groups, cycloalkyl groups, aralkyl groups, alkoxide groups, alkadienyl groups or alkenyl groups. The hydrocarbon groups R¹, R²
 50 and R³ can contain between 1 and 20 carbon atoms and preferably from 1 to about 10 carbon atoms.

[0066] The surface modifying action is effected by adding the organometallic compound in a suitable solvent to a slurry of the support material. Contact of the organometallic compound in a suitable solvent and the support is maintained from 30 to 180 minutes and preferably from 60 to 90 minutes at a temperature in the range of 20° to 100° C. The diluent employed in slurring the support can be any of the solvents employed in solubilizing the organometallic compound and is preferably the same.

55 [0067] In order to more readily produce interpolymer compositions of controlled composition and molecular weight distribution, the constrained-geometry component catalyst and the Ziegler-type transition metal catalyst component should have different reactivity ratios. The reactivity ratio of the homogeneous catalyst may be higher than the reactivity

ratio of the heterogeneous catalyst. In such instances, the contribution of the narrow composition and molecular weight distribution polymer molecules, formed in the first reactor, to the whole interpolymer product would yield improvements in thermal resistance and crystallization behavior of the resin. Preferably, but not limiting, the reactivity ratio of the homogeneous catalyst introduced into the first reactor should be lower than the reactivity ratio of the heterogeneous catalyst in order to have the most benefit of a simplified process and to produce interpolymers of the most suitable compositions.

[0058] The reactivity ratios of the metallocenes and transition metal components in general are obtained by methods well known such as, for example, as described in "Linear Method for Determining Monomer Reactivity Ratios in Copolymerization", M. Fineman and S. D. Ross, *J. Polymer Science* 5, 259 (1950) or "Copolymerization", F. R. Mayo and C. Walling, *Chem. Rev.* 46, 191 (1950).

[0059] For example, to determine reactivity ratios, the most widely used copolymerization model is based on the following equations:

here M_1 , M_2 refer to monomer molecules and M_1^* or M_2^* refer to a growing polymer chain to which monomer M_1 or M_2 has most recently attached. M_1 is typically ethylene; M_2 is typically an α -olefin comonomer.

[0070] The k_{ij} values are the rate constants for the indicated reactions. In this case, k_{11} represents the rate at which an ethylene unit inserts into a growing polymer chain in which the previously inserted monomer unit was also ethylene. The reactivity rates follows as: $r_1 = k_{11}/k_{12}$ and $r_2 = k_{22}/k_{21}$ wherein k_{11} , k_{12} , k_{22} , and k_{21} are the rate constants for ethylene (1) or comonomer (2) addition to a catalyst site where the last polymerized monomer is ethylene (k_{1X}) or comonomer (2) (k_{2X}). A lower value of r_1 for a particular catalyst translates into the formation of an interpolymer of higher comonomer content produced in a fixed reaction environment. In a preferred embodiment of the invention, the reactivity ratio, r_1 , of the homogeneous catalyst is less than half that of the heterogeneous catalyst.

[0071] Therefore, in the desirable practice of the invention, the homogeneous catalyst produces a polymer of higher comonomer content than that of the polymer produced by the heterogeneous in a reaction environment which is low in the concentration of the comonomer. As the contents of the first reactor enter a second reactor, the concentration of the comonomer in the second reactor is reduced. Hence, the reaction environment in which the heterogeneous catalyst forms polymer is such that a polymer containing a lower comonomer content is produced. Under such reaction conditions, the polymer so formed will have a well-defined and narrow composition distribution and narrow molecular weight distribution. The resulting whole interpolymer product can be readily controlled by choice of catalysts, comonomers, and reaction temperatures in an economical and reproducible fashion. In addition, simple changes in monomer concentrations and conversions in each reactor allows the manufacture of a broad range of interpolymer products.

[0072] The heterogeneous polymers and interpolymers used to make the novel polymer compositions of the present invention can be ethylene homopolymers or, preferably, interpolymers of ethylene with at least one C_3 - C_{20} α -olefin and/or C_4 - C_{18} diolefins. Heterogeneous copolymers of ethylene and 1-octene are especially preferred.

Polymerization

[0073] The polymerization conditions for manufacturing the polymers of the present invention are generally those useful in the solution polymerization process, although the application of the present invention is not limited thereto. Slurry and gas phase polymerization processes are also believed to be useful, provided the proper catalysts and polymerization conditions are employed.

[0074] Multiple reactor polymerization processes are particularly useful in the present invention, such as those disclosed in USP 3,914,342 (Mitchell). The multiple reactors can be operated in series or in parallel, with at least one constrained geometry catalyst employed in one of the reactors and at least one heterogeneous catalyst employed in at least one other reactor. Preferably, the polymerization temperature of the constrained geometry portion of the polymerization is lower than that of the heterogeneous polymerization portion of the reaction.

[0075] According to one embodiment of the present process, the polymers are produced in a continuous process, as opposed to a batch process. Preferably, the polymerization temperature is from 20°C to 250°C, using constrained

geometry catalyst technology. In the generally preferred embodiments where a narrow molecular weight distribution polymer (M_w/M_n of from 1.5 to 2.5) having a higher I_{10}/I_2 ratio (e.g., I_{10}/I_2 of at least 7, preferably at least 8, especially at least 9) is desired, the ethylene concentration in the reactor is preferably not more than 8 percent by weight of the reactor contents, especially not more than 4 percent by weight of the reactor contents. Preferably, the polymerization is performed in a solution polymerization process. Generally, manipulation of I_{10}/I_2 while holding M_w/M_n relatively low for producing the polymers described herein is a function of reactor temperature and/or ethylene concentration. Reduced ethylene concentration and higher temperature generally produce higher I_{10}/I_2 materials.

[0076] Separation of the interpolymer compositions from the high temperature polymer solution can be accomplished by use of devolatilizing apparatus known to those skilled in the art. Examples include USP 5,084,134 (Mattiusi et al.), USP 3,014,702 (Oldershaw et al.), USP 4,808,262 (Aneja et al.), USP 4,564,063 (Tollar), USP 4,421,162 (Tollar) or USP 3,239,197 (Tollar).

Molecular Weight Distribution Determination

[0077] The interpolymer product samples analyzed by gel permeation chromatography (GPC) on a Waters 150C high temperature chromatographic unit equipped with three mixed porosity columns (Polymer Laboratories 10^3 , 10^4 , 10^5 , and 10^6), operating at a system temperature of 140°C . The solvent is 1,2,4-trichlorobenzene, from which 0.3 percent by weight solutions of the samples are prepared for injection. The flow rate is 1.0 milliliters/minute and the injection size is 200 microliters.

[0078] The molecular weight determination is deduced by using narrow molecular weight distribution polystyrene standards (from Polymer Laboratories) in conjunction with their elution volumes. The equivalent polyethylene molecular weights are determined by using appropriate Mark-Houwink coefficients for polyethylene and polystyrene (as described by Williams and Word in Journal of Polymer Science, Polymer Letters, Vol. 6, (621) 1968) to derive the following equation:

$$M_{\text{polyethylene}} = a \cdot (M_{\text{polystyrene}})^b$$

In this equation, $a = 0.4316$ and $b = 1.0$. Weight average molecular weight, M_w , is calculated in the usual manner according to the following formula: $M_w = \sum w_i \cdot M_i$, where w_i and M_i are the weight fraction and molecular weight, respectively, of the i th fraction eluting from the GPC column.

[0079] For the interpolymer fractions and whole interpolymers described herein, the term "narrow molecular weight distribution" means that the M_w/M_n of the interpolymer (or fraction) is less than 3, preferably from 2 to 3. The M_w/M_n of the "narrow molecular weight distribution" interpolymer (or fraction) can also be described by the following equation: $(M_w/M_n) \leq (I_{10}/I_2) - 4.63$.

[0080] For the interpolymer fractions and whole interpolymers described herein, the term "broad molecular weight distribution" means that the M_w/M_n of the interpolymer (or fraction) is greater than 3, preferably from 3 to 5.

Crystallization Onset Temperature Measurement

[0081] The crystallization onset temperatures of the polyethylene compositions described herein are measured using differential scanning calorimetry (DSC). Each sample to be tested is made into a compression molded plaque according to ASTM D 1928. The plaques are then thinly sliced at room temperature using a Reichert Microtome or a razor blade to obtain samples having a thickness of about 15 micrometers. About 5 milligrams of each sample to be tested is placed in the DSC pan and heated to about 180°C , held at that temperature for 3 minutes to destroy prior heat history, cooled to -50°C at a rate of $10^\circ\text{C}/\text{minute}$ and held at that temperature for 2 minutes. The crystallization onset temperature and the peak temperature are recorded by the DSC as the temperature at which crystallization begins and the temperature at which the sample is as fully crystallized as possible, respectively, during the cooling period from 180°C to -50°C .

[0082] Other useful physical property determinations made on the novel interpolymer compositions described herein include:

[0083] Melt flow ratio (MFR): measured by determining " I_{10} " (according to ASTM D-1238, Condition $190^\circ\text{C}/10$ kg (formerly known as "Condition (N)") and dividing the obtained I_{10} by the I_2 . The ratio of these two melt index terms is the melt flow ratio and is designated as I_{10}/I_2 . For the homogeneous portion of the interpolymer composition, the I_{10}/I_2 ratio is generally greater than or equal to 5.63 and preferably from 5.8 to 8.5. For the heterogeneous portion of the interpolymer composition, the I_{10}/I_2 ratio is typically from 6.8 to 9.5. The I_{10}/I_2 ratio for the whole interpolymer compositions is typically from 6.8 to 10.5.

2% Secant Modulus: using a method similar to ASTM D 882, except that 4 specimens are used, a 4 (18 cm) inch

gauge length is used and the conditioning period is 24 hours;

Clarity: measured by specular transmittance according to ASTM D 1746, except that the samples are conditioned for 24 hours;

Haze: measured according to ASTM D 1003.

Young's modulus, yield strength and elongation, break strength and elongation, and toughness: using a method similar to ASTM D 882, except that 4 specimens are used and are pulled at 20 inches per minute (50 cm/min) using a 2 inch (5 cm) gauge length;

Spencer Impact: using a method similar to ASTM D 3420, procedure "B", except that the maximum capacity is 1600 grams, the values are normalized for sample thickness and the conditioning period has been shortened from 40 hours to 24 hours; and

Tensile Tear: using a method similar to ASTM D 1938, except that 4 specimens are used.

[0084] Useful articles which can be made from such interpolymer compositions include films (e.g., cast film, blown film or extrusion coated types of film), fibers (e.g., staple fibers, melt blown fibers or spunbonded fibers (using, e.g., systems as disclosed in USP 4,340,563, USP 4,663,220, USP 4,668,566, or USP 4,322,027), and gel spun fibers (e.g., the system disclosed in USP 4,413,110)), both woven and nonwoven fabrics (e.g., spunlaced fabrics disclosed in USP 3,485,706) or structures made from such fibers (including, e.g., blends of these fibers with other fibers, e.g., PET or cotton)), and molded articles (e.g., blow molded articles, injection molded articles and rotomolded articles)

[0085] Films particularly benefit from such interpolymer compositions. Films and film structures having the novel properties described herein can be made using conventional hot blown film fabrication techniques or other biaxial orientation process such as tenter frames or double bubble processes. Conventional hot blown film processes are described, for example, in The Encyclopedia of Chemical Technology, Kirk-Othmer, Third Edition, John Wiley & Sons, New York, 1981, Vol. 16, pp. 416-417 and Vol. 18, pp. 191-192. Biaxial orientation film manufacturing process such as described in a "double bubble" process as in U.S. Patent 3,456,044 (Pahlke), and the processes described in U.S. Patent 4,865,902 (Golike et al.), U.S. Patent 4,352,849 (Mueller), U.S. Patent 4,820,557 (Warren), U.S. Patent 4,927,708 (Herran et al.), U.S. Patent 4,963,419 (Lustig et al.), and U.S. Patent 4,952,451 (Mueller) can also be used to make novel film structures from the novel interpolymer compositions. Novel property combinations of such films include unexpectedly high machine and cross direction secant modulus, both first and second machine and cross direction yield, dart impact, cross direction tensile, clarity, 20° gloss, 45° gloss, low haze, low blocking force and low coefficient of friction (COF).

[0086] In addition, these interpolymer compositions have better resistance to melt fracture. An apparent shear stress vs. apparent shear rate plot is used to identify the melt fracture phenomena. According to Ramamurthy in Journal of Rheology, 30(2), 337-357, 1986, above a certain critical flow rate, the observed extrudate irregularities may be broadly classified into two main types: surface melt fracture and gross melt fracture.

[0087] Surface melt fracture occurs under apparently steady flow conditions and ranges in detail from loss of specular gloss to the more severe form of "sharkskin". In this disclosure, the onset of surface melt fracture is characterized at the beginning of losing extrudate gloss at which the surface roughness of extrudate can only be detected by 40X magnification. The critical shear rate at onset of surface melt fracture for the substantially linear olefin polymers is at least 50 percent greater than the critical shear rate at the onset of surface melt fracture of a linear olefin polymer having about the same 12 and Mw/Mn.

[0088] Gross melt fracture occurs at unsteady flow conditions and ranges in detail from regular (alternating rough and smooth, helical, etc.) to random distortions. For commercial acceptability, (e.g., in blown film products), surface defects should be minimal, if not absent. The critical shear rate at onset of surface melt fracture (OSMF) and onset of gross melt fracture (OGMF) will be used herein based on the changes of surface roughness and configurations of the extrudates extruded by a GER.

Example 1

Homogeneous Catalyst Preparation

[0089] A known weight of the constrained-geometry organometallic complex $[(\text{CH}_3)_4\text{C}_5\text{Si}-(\text{CH}_3)_2\text{Si}-\text{N}-(\text{t}-\text{C}_4\text{H}_9)]\text{Ti}(\text{CH}_3)_2$ was dissolved in Isopar E to give a clear solution with a concentration of Ti of 0.005M. A similar solution of the activator complex, tris(perfluorophenyl)borane (0.010M) was also prepared. A catalyst composition of a few mL total volume was prepared by adding 2.0 mL of Isopar E solution of Ti reagent, 2.0 mL of the borane (for B:Ti = 2:1) and 2 mL Isopar E to a 4 oz (100 ml) glass bottle. The solution was mixed for a few minutes and transferred by syringe to a catalyst injection cylinder on the polymerization reactor.

Heterogeneous Catalyst Preparation

[0090] A heterogeneous Ziegler-type catalyst was prepared substantially according to USP 4,612,300 (Ex. P.), by sequentially adding to a volume of Isopar E, a slurry of anhydrous magnesium chloride in Isopar E, a solution of EtAlCl_2 in hexane, and a solution of $\text{Ti}(\text{O}-i\text{Pr})_4$ in Isopar E, to yield a composition containing a magnesium concentration of 0.17M and a ratio of Mg/Al/Ti of 40/12/3. An aliquot of this composition containing 0.064 mmol of Ti which was treated with a dilute solution of Et_3Al to give an active catalyst with a final Al/Ti ratio of 8/1. This slurry was then transferred to a syringe until it was required for injection into the polymerization reactor.

Polymerization

[0091] The polymerization described in this example demonstrates a process for the use of two catalysts, employed sequentially, in two polymerization reactors. A stirred, one-gallon (3.79L) autoclave reactor is charged with 2.1 L of Isopar™ E (made by Exxon Chemical) and 388 mL of 1-octene comonomer and the contents are heated to 150°C. The reactor is next charged with ethylene sufficient to bring the total pressure to 450 psig (3.2 MPa). A solution containing 0.010 mmol of the active organometallic catalyst described in the catalyst preparation section is injected into the reactor using a high pressure nitrogen sweep. The reactor temperature and pressure are maintained constant at the desired final pressure and temperature by continually feeding ethylene during the polymerization run and cooling the reactor as necessary. After a 10 minute reaction time, the ethylene is shut off and the reactor is depressured to 100 psig (0.8 MPa). Hydrogen is admitted to the reactor and the contents heated. A slurry of the heterogeneous catalyst containing 0.0064 mmol Ti prepared as described in the catalyst preparation section is injected into the reactor using a high pressure nitrogen sweep. The reactor is then continually fed ethylene at 450 psig (3.2 MPa) and the reaction temperature quickly rose to 185°C where the polymerization is sustained for an additional 10 minutes. At this time the reactor is depressured and the hot polymer-containing solution transferred into a nitrogen-purged resin kettle containing 0.2 g Irganox 1010 antioxidant as a stabilizer. After removal of all the solvent in vacuo, the sample is then weighed (yield 270 g) to determine catalyst efficiencies (344300 g PE/ g Ti).

Examples 2 and 3

[0092] Examples 2 and 3 are carried out as in Example 1 except using the catalyst amounts and reactor temperatures described in Table 1. The overall catalyst efficiencies are also shown in the Table.

[0093] The polymer products of Examples 1-3 are tested for various structural, physical and mechanical properties and the results are given in Tables 2, 2A and 2B. Comparative Example A is Attane® 4001 polyethylene and comparative example B is Attane® 4003. Both comparative examples are made by The Dow Chemical Company and are commercial ethylene-octene copolymers produced under solution process conditions using a typical commercial Ziegler-type catalyst. The data show the polymers of the invention have more narrow molecular weight distributions (M_w/M_n), higher melting points, better crystallization properties (i.e., higher crystallization onset temperatures) and, surprisingly, higher modulus than the commercial comparative examples A and B. The polymers of the invention surprisingly also show better optical properties (i.e., higher clarity and lower haze) than the comparative polymers, even though the polymers have about the same density. In addition, the polymers of the invention show better strength, toughness, tear and impact properties.

Example 410 Homogeneous Catalyst Preparation

[0094] A known weight of the constrained-geometry organometallic complex $[(CH_3)_4C_5]-(CH_3)_2Si-N-(t-C_4H_9)Ti(CH_3)_2$ is dissolved in Isopar E to give a clear solution with a concentration of Ti of 0.001M. A similar solution of the activator complex, tris(perfluorophenyl)borane (0.002M) is also prepared. A catalyst composition of a few mL total volume is prepared by adding 1.5 mL of Isopar E solution of Ti reagent, 1.5 mL of the borane (for B:Ti = 2:1) and 2 mL of a heptane solution of methylaluminoxane (obtained commercially from Texas Alkyls as MMAO Type 3A) containing 0.015 mmol Al to a 4 oz (100 ml) glass bottle. The solution is mixed for a few minutes and transferred by syringe to a catalyst injection cylinder on the polymerization reactor.

20 Heterogeneous Catalyst Preparation

[0095] A heterogeneous Ziegler-type catalyst is prepared similarly to that in Ex. 1 to give an active catalyst containing 0.009 mmol Ti and a final Al/Ti ratio of 8/1. This slurry is then transferred to a syringe in preparation for addition to the catalyst injection cylinder on the polymerization reactor.

25 Polymerization

[0096] A stirred, one-gallon (3.79L) autoclave reactor is charged with 2.1 L of Isopar™ E (made by Exxon Chemical) and 168 mL of 1-octene comonomer and the contents are heated to 120°C. The reactor is next charged with hydrogen and then with ethylene sufficient to bring the total pressure to 450 psig (3.2MPa). A solution containing 0.0015 mmol of the active organometallic catalyst described in the catalyst preparation section is injected into the reactor using a high pressure nitrogen sweep. The reactor temperature and pressure are maintained at the initial run conditions. After a 10 minute reaction time, the ethylene is shut off and the reactor is depressured to 100 psig (0.8MPa). At this time, an additional 168 mL of 1-octene is added to the reactor along with additional hydrogen and the contents heated. A slurry of the heterogeneous catalyst containing 0.009 mmol Ti prepared as described in the catalyst preparation section is injected into the reactor using a high pressure nitrogen sweep. The reactor is then continually fed ethylene at 450 psig (3.2MPa) and the reaction temperature quickly rises to 189°C where the polymerization is sustained for an additional 10 minutes. At this time the reactor is depressured and the hot polymer-containing solution transferred into a nitrogen-purged resin kettle containing 0.2 g Irganox™ 1010 (a hindered phenolic antioxidant made by Ciba Geigy Corp.) as a stabilizer. After removal of all the solvent in vacuo, the sample is then weighed (yield 202 g) to determine catalyst efficiencies (401630 g PE/ g Ti).

Examples 5-7

45 [0097] Examples 5-7 are carried out as in Example 4 except using the catalysts described in Example 1 and the catalyst amounts and reactor conditions described in Tables 3 and 3A. The overall catalyst efficiencies are also shown in Tables 3 and 3A.

[0098] These examples show that the reaction conditions can be readily controlled to vary the composition and molecular weight distribution of the polymer through a simple change in catalyst amounts and monomer concentrations. Table 4 shows that the interpolymers produced in these examples have a broader molecular weight distribution than those of the earlier examples demonstrating a unique feature of the process control. The physical and mechanical properties still show surprising enhancements over typical commercial copolymers of comparable molecular weight and composition, particularly in strength, impact and tear properties. Comparing examples 4 and 5 with comparative example A (as well as by comparing examples 6 and 7 with comparative example B) shows that the crystallization properties of the polymers of the invention are largely unaffected by broadening the M_w/M_n .

Example 8Homogeneous Catalyst Preparation

[0099] A known weight of the constrained-geometry organometallic complex $[(\text{CH}_3)_4\text{C}_5\text{Si}-(\text{CH}_3)_2\text{Si}-\text{N}-(\text{t-C}_4\text{H}_9)]\text{Ti}(\text{CH}_3)_2$ is dissolved in Isopar E to give a clear solution with a concentration of Ti of 0.001M. A similar solution of the activator complex, tris(perfluorophenyl)borane (0.002M) is also prepared. A catalyst composition of a few mL total volume is prepared by adding 1.5 mL of Isopar E solution of Ti reagent, 1.5 mL of the borane (for B:Ti = 2:1) and 2 mL of a heptane solution of methylaluminoxane (obtained commercially from Texas Alkyls as MMAO) containing 0.015 mmol Al to a 4 oz (100 ml) glass bottle. The solution is mixed for a few minutes and transferred by syringe to a catalyst injection cylinder on the polymerization reactor.

Heterogeneous Catalyst Preparation

[0100] A heterogeneous Ziegler-type catalyst is prepared similarly to that in Ex. 1 to give an active catalyst containing 0.009 mmol Ti and a final Al/Ti ratio of 8/1. This slurry is then transferred to a syringe in preparation for addition to the catalyst injection cylinder on the polymerization reactor.

Polymerization

[0101] The polymerization described in this example demonstrates a process for the use of two catalysts, employed sequentially, in two polymerization reactors. A stirred, one-gallon (3.79L) autoclave reactor is charged with 2.1 L of Isopar[™] E (made by Exxon Chemical) and 168 mL of 1-octene comonomer and the contents are heated to 120°C. The reactor is next charged with hydrogen and then with ethylene sufficient to bring the total pressure to 450 psig (3.2 MPa). A solution containing 0.0015 mmol of the active organometallic catalyst described in the catalyst preparation section is

injected into the reactor using a high pressure nitrogen sweep. The reactor temperature and pressure are maintained at the initial run conditions. After a 10 minute reaction time, the ethylene is shut off and the reactor is depressured to 100 psig (0.8 MPa). At this time, an additional 168 mL of 1-octene is added to the reactor along with additional hydrogen and the contents heated. A slurry of the heterogeneous catalyst containing 0.009 mmol Ti prepared as described in the catalyst preparation section is injected into the reactor using a high pressure nitrogen sweep. The reactor is then continually fed ethylene at 450 psig (3.2MPa) and the reaction temperature quickly rises to 189°C where the polymerization is sustained for an additional 10 minutes. At this time the reactor is depressured and the hot polymer-containing solution transferred into a nitrogen-purged resin kettle containing 0.2 g Irganox™ 1010 (a hindered phenolic antioxidant made by Ciba Geigy Corp.) as a stabilizer. After removal of all the solvent in vacuo, the sample is then weighed (yield 202 g) to determine catalyst efficiencies (401630 g PE/ g Ti).

Examples 9-14

[0102] Examples 9-14 are carried out as in Example 8 except using the catalysts described in Example 1 and the catalyst amounts and reactor conditions described in Tables 5 and 5A. The overall catalyst efficiencies are also shown in the Tables.

[0103] These examples show the ability to readily control the reaction conditions to vary the composition and molecular weight distribution of the polymer through a simple change in catalyst amounts and monomer concentrations. The polymers produced in these Examples show a broader molecular weight distribution than those of the earlier examples showing a unique feature of the process control. The physical and mechanical properties still show surprising enhancements over typical commercial copolymers of comparable molecular weight and composition, particularly in strength, impact and tear properties.

[0104] Comparative Example C is Dowlex® 2045, a commercial ethylene/1-octene copolymer made by The Dow Chemical Company. Comparative Example D is Dowlex® 2047, a commercial LLDPE ethylene/1-octene copolymer made by The Dow Chemical Company.

[0105] The data in Table 6 show that the molecular weight distribution (M_w/M_n) can surprisingly remain relatively low, demonstrating a unique feature of the process control of the invention.

[0106] In step (B) of the Second Process, the ethylene and α -olefin materials may be present as unreacted materials in the reaction product from step (A) or they can each be added to the polymerization reaction mixture in step (B) as needed to make the desired interpolymer. In addition, hydrogen or other telogen can be added to the polymerization mixture of step (B) to control molecular weight.

Example 15

[0107] Example 15 is an *in-situ* blend made according to a continuous polymerization process. In particular, ethylene is fed into a first reactor at a rate of 52 lb/hr (24 kg/hr). Prior to introduction into the first reactor, the ethylene is combined with a diluent mixture comprising ISOPAR™ E hydrocarbon (available from Exxon) and 1-octene. With respect to the first reactor, the 1-octene:ethylene ratio is 9.6:1 (mole percent) and the diluent:ethylene ratio is 9.9:1 (weight). A homogenous constrained geometry catalyst and cocatalyst such as are described in Example 8 above and introduced into the first reactor. The catalyst and cocatalyst concentrations in the first reactor are 0.0030 and 0.0113 molar, respectively. The catalyst and cocatalyst flow rates into the first reactor are 0.537 lbs/hr (0.224 kg/hr) and 0.511 lbs/hr (0.232 kg/hr), respectively. The polymerization is conducted at a reaction temperature of 120°C. The polymer of the first reactor is an ethylene/1-octene copolymer and is estimated to have a density of 0.906 g/cm³, a melt flow ratio (I_{10}/I_2) of about 8-10 and a molecular weight distribution (M_w/M_n) of 2.2.

[0108] The reaction product of the first reactor is transferred to a second reactor. The ethylene concentration in the exit stream from the first reactor is less than four percent, indicating the presence of long chain branching as described in U.S. Patent No. 5, 272,236.

[0109] Ethylene is further fed into a second reactor at a rate of 58 lbs/hr (26 kg/hr). Prior to introduction into the second reactor, the ethylene and a stream of hydrogen are combined with a diluent mixture comprising ISOPAR™ E hydrocarbon (available from Exxon) and 1-octene. With respect to the second reactor, the 1-octene:ethylene ratio is 2.9:1 (mole percent), the diluent:ethylene ratio is 2.8 (weight), and the hydrogen:ethylene ratio is 0.106 (mole percent). A heterogeneous Ziegler catalyst and cocatalyst such as are described in Example 1 above are introduced into the second reactor. The catalyst and cocatalyst concentrations in the second reactor are 0.0023 and 0.0221 molar, respectively. The catalyst and cocatalyst flow rates into the second reactor are 1.4 lbs/hr (0.64 kg/hr) and 0.858 lbs/hr (0.39 kg/hr), respectively. The polymerization is conducted at a reaction temperature of 190°C. The polymer of the second reactor is an ethylene/1-octene copolymer and estimated to have a density of 0.944 g/cm³ and a melt index (I_2) of 1.5 g/10 minutes.

[0110] The total composition comprises 43 percent by weight of the polymer of the first reactor and 57 percent by weight of the polymer of the second reactor. The total composition has a melt index (I_2) of 0.53 g/10 minutes, a density of 0.9246 g/cm³, a melt flow ratio (I_{10}/I_2) of 7.83, and a molecular weight distribution (M_w/M_n) of 2.8.

Claims

1. A process for preparing an ethylene/ α -olefin interpolymer composition, characterized by:

(A) reacting by contacting ethylene and at least one other α -olefin under solution polymerization conditions in the presence of a homogeneous catalyst composition in at least one reactor to produce a solution of a first interpolymer which has a narrow composition distribution, (i.e., one which has a composition distribution branch index (CDBI) of greater than 50 percent where CDBI is defined at the weight percentage of polymer molecules having a comonomer content within 50 percent of the median total comonomer content as measured by the TREF technique defined herein), and a narrow molecular weight distribution (i.e. a molecular weight distribution such that M_w/M_n is less than 3), wherein 15% or less of the first interpolymer has a degree of branching of less than or equal to 2 methyls/1000 carbons and is lacking a measurable homopolymer fraction as measured by the TREF technique, and wherein the homogeneous catalyst composition contains either no aluminum cocatalyst or contains an amount of aluminum cocatalyst which will give rise to a detectable aluminum residue in the product of less than or equal to 250 ppm,

(B) reacting by contacting ethylene and at least one other α -olefin under solution polymerization conditions and at a higher polymerization reaction temperature than used in step (A) in the presence of a heterogeneous Ziegler catalyst in at least one other reactor to produce a solution of a second interpolymer which has a broad composition distribution (i.e. a composition distribution such that the composition has a homopolymer fraction as measured by the TREF technique and has multiple melting peaks), and a broad molecular weight distribution (i.e. a molecular weight distribution such that M_w/M_n is greater than 3), wherein 10 weight percent or more of the second interpolymer has a degree of branching of less than 2 methyls/1000 carbons, and wherein 25 weight percent or less of the second interpolymer has a degree of branching of 25 methyls/1000 carbons or more, wherein the Ziegler catalyst comprises

- (i) a solid support component derived from a magnesium halide or silica, and
- (ii) a transition metal component represented by the formula: $\text{TrX}'_{4-q}(\text{OR}^1)_q$, $\text{TrX}'_{4-q}(\text{R}^2)_q$, VOX'_3 or $\text{VO}(\text{OR}^1)_3$, wherein:

Tr is a Group, IVB, VB, or VIB metal,

q is 0 or a number equal to or less than 4,

X' is a halogen, and

R^1 is an alkyl group, aryl group or cycloalkyl group having from 1 to 20 carbon atoms, and

R^2 is an alkyl group, aryl group, aralkyl group, or substituted aralkyl group, and

(C) combining the solution of the first interpolymer with the solution of the second interpolymer to form a polymer solution comprising the ethylene- α -olefin interpolymer composition, and

(D) removing the solvent from the polymer solution of step (C) and recovering the ethylene- α -olefin interpolymer composition.

2. A process for preparing an ethylene/ α -olefin interpolymer composition, characterized by:

(A) polymerizing ethylene and at least one other α -olefin under solution polymerization conditions in at least one reactor containing a homogeneous catalyst composition to produce a solution of a first interpolymer which has a narrow composition distribution, (i.e., one which has a composition distribution branch index (CDBI) of greater than 50 percent where CDBI is defined at the weight percentage of polymer molecules having a comonomer content within 50 percent of the median total comonomer content as measured by the TREF technique defined herein), and a narrow molecular weight distribution (i.e. a molecular weight distribution such that M_w/M_n is less than 3), wherein 15% or less of the first interpolymer has a degree of branching of less than or equal to 2 methyls/1000 carbons and is lacking a measurable homopolymer fraction as measured by the TREF technique, and wherein the homogeneous catalyst composition contains either no aluminum cocatalyst or contains an amount of aluminum cocatalyst which will give rise to a detectable aluminum residue in the product of less than or equal to 250 ppm,

(B) sequentially passing the interpolymer solution of (A) into at least one other reactor containing a heterogeneous Ziegler catalyst, ethylene and at least one other α -olefin, under solution polymerization conditions and at a higher polymerization reaction temperature than used in step (A) to produce a solution comprising the ethylene/ α -olefin interpolymer composition, wherein the Ziegler catalyst comprises

- (i) a solid support component derived from a magnesium halide or silica, and

- (ii) a transition metal component represented by the formula: $\text{TrX}'_{4-q}(\text{OR}^1)_q$, $\text{TrX}'_{4-q}(\text{R}^2)_q$, VOX'_3 or

VO(OR¹)₃, wherein:

Tr is a Group, IVB, VB, or VIB metal,

q is 0 or a number equal to or less than 4,

X' is a halogen, and

R¹ is an alkyl group, aryl group or cycloalkyl group having from 1 to 20 carbon atoms, and

R² is an alkyl group, aryl group, aralkyl group, or substituted aralkyl group, and

(C) combining the solution of the first interpolymers with the solution of the second interpolymers to form a polymer solution comprising the ethylene- α -olefin interpolymers composition, and

(D) removing the solvent from the polymer solution of step (C) and recovering the ethylene- α -olefin interpolymers composition.

3. The process of any one of the preceding claims, wherein the α -olefin is 1-octene.
4. The process of any one of the preceding claims, wherein the homogeneous catalyst composition comprises a metal co-ordination complex comprising a metal of group 4 of the Periodic Table of the Elements and a delocalised π -bonded moiety substituted with a constrain-inducing moiety, said complex having a constrained geometry about the metal atom such that the angle at the metal between the centroid of the delocalised, substituted π -bonded moiety and the centre of at least one remaining substituent is less than such angle in a similar complex containing a similar π -bonded moiety lacking in such constrain-inducing substituent, and provided further that for such complexes comprising more than one delocalised, substituted π -bonded moiety, only one thereof for each metal atom of the complex is a cyclic, delocalised, substituted π -bonded moiety.
5. The process of any one of the preceding claims wherein the homogeneous catalyst composition further comprises an activating cocatalyst.
6. The process of any one of Claims 1 to 5 wherein the homogeneous catalyst composition comprises a metal co-ordination complex corresponding to the formula:

wherein:

M is a metal of group 4 of the Periodic Table of the Elements;

Cp* is a cyclopentadienyl or substituted cyclopentadienyl group bound in an η^5 bonding mode to M;

Z is a moiety comprising boron, or a member of group 14 of the Periodic Table of the Elements, and optionally sulfur or oxygen, said moiety having up to 20 non-hydrogen atoms, and optionally Cp* and Z together form a fused ring system;

X independently each occurrence is an anionic ligand group having up to 30 non-hydrogen atoms;

n is 1 or 2; and

Y is an anionic or nonanionic ligand group bonded to Z and M comprising nitrogen, phosphorus, oxygen or sul-

fur and having up to 20 non-hydrogen atoms, optionally Y and Z together form a fused ring system.

7. The process of any one of Claims 1 to 5 wherein the homogeneous catalyst composition comprises a metal co-ordination complex corresponding to the formula:

wherein:

R' each occurrence is independently selected from the group consisting of hydrogen, alkyl, aryl, and silyl, and combinations thereof having up to 20 non-hydrogen atoms;

X each occurrence independently is selected from the group consisting of hydride, halo, alkyl, aryl, silyl, aryloxy, alkoxy, amide, siloxy and combinations thereof having up to 20 non-hydrogen atoms;

Y is -O-, -S-, -NR*, -PR*, or a neutral two electron donor ligand selected from the group consisting of OR*, SR*, NR*₂ or PR*₂;

M is a metal of group 4 of the Periodic Table of the Elements; and

Z is SiR*₂, CR*₂, SiR*₂SiR*₂, CR*₂CR*₂, CR*=CR*, CR*₂SiR*₂, BR*; wherein

R* each occurrence is independently selected from the group consisting of hydrogen, alkyl, aryl, silyl, halogenated alkyl, halogenated aryl groups having up to 20 non-hydrogen atoms, and mixtures thereof, or two or more R* groups from Y, Z, or both Y and Z form a fused ring system; and n is 1 or 2.

8. The process of any one of Claims 1 to 5 wherein the homogeneous catalyst composition comprises an amidosilane- or amidoalkanediyl- compound corresponding to the formula:

wherein:

M is titanium, zirconium or hafnium, bound in an η^5 bonding mode to the cyclopentadienyl group;

R' each occurrence is independently selected from the group consisting of hydrogen, alkyl and aryl and combinations thereof having up to 7 carbon atoms, or silyl;

E is silicon or carbon;

X independently each occurrence is hydride, halo, alkyl, aryl, aryloxy or alkoxy of up to 10 carbons, or silyl;

m is 1 or 2; and

n is 1 or 2.

9. The process of any one of Claims 1 to 5 wherein the homogeneous catalyst composition comprises an ionic catalyst having a limiting charge separated structure corresponding to the formula:

wherein:

M is a metal of group 4 of the Periodic Table of the Elements;

Cp⁺ is a cyclopentadienyl or substituted cyclopentadienyl group bound in an η^5 bonding mode to M;

Z is a moiety comprising boron, or a member of group 14 of the Periodic Table of the Elements, and optionally sulfur or oxygen, said moiety having up to 20 non-hydrogen atoms, and optionally Cp⁺ and Z together form a fused ring system;

X independently each occurrence is an anionic ligand group having up to 30 non-hydrogen atoms;

n is 1 or 2; and

XAⁿ⁻ is $\text{X}(\text{B}(\text{C}_6\text{F}_5)_3)_n$.

10. The process of any one of the preceding claims wherein the homogeneous catalyst composition has a reactivity ratio less than half that of the heterogeneous catalyst.

11. An ethylene/ α -olefin interpolymer composition producible by the process of any one of the preceding claims.

Patentansprüche

1. Verfahren zur Herstellung einer Ethylen/ α -Olefin-Interpolymerzusammensetzung, dadurch gekennzeichnet, daß man:

(A) durch Inkontaktbringen Ethylen und mindestens ein weiteres α -Olefin unter Lösungspolymerisationsbedingungen in Gegenwart einer homogenen Katalysatorzusammensetzung in mindestens einem Reaktor umsetzt, um eine Lösung eines ersten Interpolymers herzustellen, welches eine enge Zusammensetzungsverteilung (d.h. eine, die einen Zusammensetzungsverteilungsverzweigungsindex (CDBI) von größer als 50 % aufweist, worin CDBI definiert ist als der Gewichtsanteil von Polymermolekülen, die einen Comonomergehalt innerhalb von 50 % des mittleren Gesamtcomonomergehalts, wie durch die hierin definierte TREF-Technik gemessen, aufweisen) und eine enge Molekulargewichtsverteilung (d.h. ein derartige Molekulargewichtsverteilung, daß M_w/M_n kleiner als 3 ist) aufweist, worin 15 % oder weniger des ersten Interpolymers einen Verzweigungsgrad

von kleiner als oder gleich 2 Methyl/1000 Kohlenstoffe aufweist und frei ist von einer meßbaren Homopolymerfraktion, wie durch die TREF-Technik gemessen, und worin die homogene Katalysatorzusammensetzung entweder keinen Aluminiumcokatalysator enthält oder eine Menge an Aluminiumcokatalysator enthält, die einen nachweisbaren Aluminiumrückstand in dem Produkt von weniger als oder gleich 250 ppm verursacht,

(B) durch Inkonaktbringen Ethylen und mindestens ein weiteres α -Olefin unter Lösungspolymerisationsbedingungen und bei einer höheren Polymerisationsreaktionstemperatur als in Schritt (A) verwendet in der Gegenwart eines heterogenen Ziegler-Katalysators in mindestens einem weiteren Reaktor umgesetzt, um eine Lösung eines zweiten Interpolymers herzustellen, welches eine breite Zusammensetzungsverteilung (d.h. eine derartige Zusammensetzungsverteilung, daß die Zusammensetzung eine Homopolymerfraktion, wie durch die TREF-Technik gemessen, aufweist und mehrere Schmelzpunkte aufweist), und eine breite Molekulargewichtsverteilung (d.h. eine derartige Molekulargewichtsverteilung, daß M_w/M_n größer als 3 ist) aufweist, worin 10 Gew.-% oder mehr des zweiten Interpolymers einen Verzweigungsgrad von weniger als 2 Methyl/1000 Kohlenstoffe aufweist und worin 25 Gew.-% oder weniger des zweiten Interpolymers einen Verzweigungsgrad von 25 Methyl/1000 Kohlenstoffen oder mehr aufweist, worin der Ziegler-Katalysator umfaßt

(i) eine feste Trägerkomponente, abgeleitet von einem Magnesiumhalogenid oder einem Siliciumoxid und

(ii) eine Übergangsmetallkomponente, dargestellt durch die Formel: $\text{TrX}'_{4-q}(\text{OR}^1)_q$, $\text{TrX}'_{4-q}(\text{R}^2)_q$, VOX'_3 oder $\text{VO}(\text{OR}^1)_3$, worin:

Tr ein Metall der Gruppe IVB, VB oder VIB ist,
q 0 oder eine Zahl gleich oder kleiner als 4 ist,
X' ein Halogen ist und

R¹ eine Alkylgruppe, eine Arylgruppe oder eine Cycloalkylgruppe mit von 1 bis 20 Kohlenstoffatomen ist, und

R² eine Alkylgruppe, eine Arylgruppe, eine Aralkylgruppe oder eine substituierte Aralkylgruppe ist und

(C) die Lösung des ersten Interpolymers mit der Lösung des zweiten Interpolymers kombiniert, um eine Polymerlösung zu bilden, die die Ethylen- α -Olefin-Interpolymerzusammensetzung umfaßt und

(D) das Lösungsmittels aus der Polymerlösung von Schritt (C) entfernt und die Ethylen- α -Olefin-Interpolymerzusammensetzung gewinnt.

2. Verfahren zur Herstellung einer Ethylen/ α -Olefin-Interpolymer-Zusammensetzung, gekennzeichnet durch:

(A) Polymerisieren von Ethylen und mindestens einem weiteren α -Olefin unter Lösungspolymerisationsbedingungen in mindestens einem Reaktor, der eine homogene Katalysatorzusammensetzung enthält, um eine Lösung eines ersten Interpolymers herzustellen, welches eine enge Zusammensetzungsverteilung (d.h. eine, die einen Zusammensetzungsverteilungsverzweigungsindex (CDBI) von größer als 50 % aufweist, worin CDBI definiert ist als der Gewichtsanteil von Polymermolekülen, die einen Comonomergehalt innerhalb von 50 % des mittleren Gesamtcomonomergehalts, wie durch die hierin definierte TREF-Technik gemessen, aufweisen) und eine enge Molekulargewichtsverteilung (d.h. eine derartige Molekulargewichtsverteilung, daß M_w/M_n kleiner als 3 ist) aufweist, worin 15 % oder weniger des ersten Interpolymers einen Verzweigungsgrad von kleiner als oder gleich 2 Methyl/1000 Kohlenstoffatome aufweist und frei von einer meßbaren Homopolymerfraktion, wie durch die TREF-Technik gemessen ist und worin die homogene Katalysatorzusammensetzung entweder keinen Aluminiumcokatalysator enthält oder eine Menge an Aluminiumcokatalysator enthält, die einen nachweisbaren Aluminiumrückstand in dem Produkt von kleiner als oder gleich 250 ppm verursacht,

(B) anschließend Leiten der Interpolymerlösung von (A) in mindestens einen weiteren Reaktor, der einen heterogenen Ziegler-Katalysator, Ethylen und mindestens ein weiteres α -Olefin enthält, unter Lösungspolymerisationsbedingungen und bei einer höheren Polymerisationsreaktionstemperatur als in Schritt (A) verwendet, um eine Lösung herzustellen, welche die Ethylen/ α -Olefin-Interpolymerzusammensetzung umfaßt, worin der Ziegler-Katalysator umfaßt:

(i) eine feste Trägerkomponente, abgeleitet von einem Magnesiumhalogenid oder einem Siliciumoxid und
(ii) eine Übergangsmetallkomponente, dargestellt durch die Formel: $\text{TrX}'_{4-q}(\text{OR}^1)_q$, $\text{TrX}'_{4-q}(\text{R}^2)_q$, VOX'_3 oder $\text{VO}(\text{OR}^1)_3$, worin:

Tr ein Metall der Gruppe IVB, VB oder VIB ist,
 q 0 oder eine Zahl gleich oder kleiner als 4 ist,
 X' ein Halogen ist und
 R¹ eine Alkylgruppe, eine Arylgruppe oder eine Cycloalkylgruppe mit von 1 bis 20 Kohlenstoffatomen
 ist, und
 R² eine Alkylgruppe, eine Arylgruppe, eine Aralkylgruppe oder eine substituierte Aralkylgruppe ist und

(C) Kombinieren der Lösung des ersten Interpolymers mit der Lösung des zweiten Interpolymers, um eine
 Polymerlösung zu bilden, welche die Ethylen- α -Olefin-Interpolymerzusammensetzung umfaßt und
 (D) Entfernen des Lösungsmittels von der Polymerlösung von Schritt (C) und Gewinnen der Ethylen- α -Olefin-
 Interpolymerzusammensetzung.

3. Verfahren nach einem der vorhergehenden Ansprüche, worin das α -Olefin 1-Octen ist.

4. Verfahren nach einem der vorhergehenden Ansprüche, worin die homogene Katalysatorzusammensetzung einen
 Metallkoordinationskomplex umfaßt, umfassend ein Metall der Gruppe 4 des Periodensystems der Elemente und
 eine delokalisierte π -gebundene Gruppe, substituiert mit einer Spannungs-induzierenden Gruppe, wobei der Kom-
 plex eine gespannte Geometrie um das Metallatom aufweist, so daß der Winkel an dem Metall zwischen dem Zen-
 trum der delokalisierten, substituierten π -gebundenen Gruppe und der Mitte von mindestens einem der übrigen
 Substituenten geringer ist als ein solcher Winkel in einem ähnlichen Komplex, der eine ähnliche π -gebundene Ein-
 heit enthält, die keinen solchen Spannungsinduzierenden Substituenten aufweist und weiterhin mit der Maßgabe,
 daß für solche Komplexe, die mehr als eine delokalisierte, substituierte π -gebundene Einheit aufweisen, nur eine
 davon für jedes Metallatom des Komplexes eine cyclische, delokalisierte, substituierte π -gebundene Einheit ist.
5. Verfahren nach einem der vorhergehenden Ansprüche, worin die homogene Katalysatorzusammensetzung weiter-
 hin einen aktivierenden Cokatalysator umfaßt.
6. Verfahren nach einem der Ansprüche 1 bis 5, worin die homogene Katalysatorzusammensetzung einen Metallko-
 ordinationskomplex umfaßt, entsprechend der Formel:

worin:

M ein Metall der Gruppe 4 des Periodensystems der Elemente ist;
 Cp* eine Cyclopentadienyl- oder eine substituierte Cyclopentadienylgruppe, gebunden in einem η^5 -Bindemo-
 dus an M ist;
 Z eine Gruppe ist, umfassend Bor oder ein Mitglied der Gruppe 14 des Periodensystems der Elemente und
 gegebenenfalls Schwefel oder Sauerstoff, wobei diese Gruppe bis zu 20 Nicht-Wasserstoffatome aufweist und
 gegebenenfalls Cp* und Z zusammen ein kondensiertes Ringsystem bilden;
 X unabhängig bei jedem Auftreten eine anionische Ligandengruppe ist, die bis zu 30 Nicht-Wasserstoffatome
 aufweist;
 n 1 oder 2 ist; und
 Y eine anionische oder nicht-anionische Ligandengruppe ist, gebunden an Z und M, welche Stickstoff, Phos-
 phor, Sauerstoff oder Schwefel umfaßt und bis zu 20 Nicht-Wasserstoffatome aufweist, wobei Y und Z gege-
 benenfalls zusammen ein kondensiertes Ringsystem bilden.

7. Verfahren nach einem der Ansprüche 1 bis 5, worin die homogene Katalysatorzusammensetzung einen Metallko-
 ordinationskomplex umfaßt, entsprechend der Formel:

worin:

R' bei jedem Auftreten unabhängig ausgewählt wird aus der Gruppe, bestehend aus Wasserstoff, Alkyl, Aryl und Silyl und Kombinationen davon mit bis zu 20 Nicht-Wasserstoffatome;

X bei jedem Auftreten unabhängig ausgewählt wird aus der Gruppe, bestehend aus Hydrid, Halogen, Alkyl, Aryl, Silyl, Aryloxy, Alkoxy, Amid, Siloxy und Kombinationen davon mit bis zu 20 Nicht-Wasserstoffatomen;

Y -O-, -S-, -NR*, -PR* oder ein neutraler Zwei-Elektronendonator-Ligand ist ausgewählt aus der Gruppe, bestehend aus OR*, SR*, NR*₂ oder PR*₂;

M ein Metall der Gruppe 4 des Periodensystems der Elemente ist; und

Z SiR*₂, CR*₂, SiR*₂SiR*₂, CR*₂CR*₂, CR*=CR*, CR*₂SiR*₂, BR* ist; worin

R* bei jedem Auftreten unabhängig ausgewählt wird aus der Gruppe, bestehend aus Wasserstoff, Alkyl-, Aryl-, Silyl-, halogenierten Alkyl-, halogenierten Arylgruppen mit bis zu 20 Nicht-Wasserstoffatomen und Gemischen davon oder zwei oder mehr R*-Gruppen von Y, Z oder beide Y und Z ein kondensiertes Ringsystem bildet; und

n 1 oder 2 ist.

8. Verfahren nach einem der Ansprüche 1 bis 5, worin die homogene Katalysatorzusammensetzung eine Amidosilan- oder Amidoalkandiyil-Verbindung umfaßt, entsprechend der Formel:

worin:

M Titan, Zirkonium oder Hafnium ist, gebunden in einem η^5 -Bindemodus an die Cyclopentadienylgruppe;

R' bei jedem Auftreten unabhängig ausgewählt wird aus der Gruppe, bestehend aus Wasserstoff, Alkyl und Aryl und Kombinationen davon mit bis zu 7 Kohlenstoffatomen oder Silyl;

E Silicium oder Kohlenstoff ist;

X unabhängig bei jedem Auftreten Hydrid, Halogen, Alkyl, Aryl, Aryloxy oder Alkoxy mit bis zu 10 Kohlenstoffatomen oder Silyl ist;

m 1 oder 2 ist; und

n 1 oder 2 ist.

9. Verfahren nach einem der Ansprüche 1 bis 5, worin die homogene Katalysatorzusammensetzung einen ionischen Katalysator umfaßt, der eine Grenzstruktur mit getrennter Ladung aufweist, entsprechend der Formel:

worin:

- M ein Metall der Gruppe 4 des Periodensystems der Elemente ist;
 Cp* eine Cyclopentadienyl- oder eine substituierte Cyclopentadienylgruppe ist, gebunden in einem η^5 -Bindemodus an M;
 Z eine Einheit ist, umfassend Bor oder ein Mitglied der Gruppe 14 des Periodensystems der Elemente und gegebenenfalls Schwefel oder Sauerstoff, wobei die Gruppe bis zu 20 Nicht-Wasserstoffatome aufweist und gegebenenfalls Cp* und Z zusammen ein kondensiertes Ringsystem bilden;
 X unabhängig bei jedem Auftreten eine anionische Ligandengruppe mit bis zu 30 Nicht-Wasserstoffatomen ist; n 1 oder 2 ist; und
 $XA^{n-} X(B(C_6F_5)_3)_3$ ist.

10. Verfahren nach einem der vorhergehenden Ansprüche, worin die homogene Katalysatorzusammensetzung ein Reaktivitätsverhältnis von kleiner als der Hälfte dessen des heterogenen Katalysators aufweist.

11. Ethylen/ α -Olefin-Interpolymerzusammensetzung, erhältlich durch das Verfahren nach einem der vorhergehenden Ansprüche.

Revendications

1. Procédé de préparation d'une composition d'interpolymères éthylène/ α -oléfine, caractérisé par les étapes consistant à :

(A) provoquer une réaction en mettant en contact de l'éthylène et au moins une autre α -oléfine dans des conditions de polymérisation en solution, en présence d'une composition de catalyseur homogène, dans au moins un réacteur, de manière à former une solution d'un premier interpolymère ayant une distribution structurale étroite (c'est-à-dire ayant un indice de ramification dans la distribution structurale (CDBI) supérieur à 50 %, l'indice CDBI étant défini comme le pourcentage en poids de molécules du polymère ayant une teneur de comonomère dans les 50 % de la teneur de comonomère totale moyenne telle que mesurée par la technique TREF définie dans la présente), et une distribution des masses moléculaires étroite (c'est-à-dire, une distribution des masses moléculaires telle que M_w/M_n est inférieur à 3), dans lequel 15 % ou moins du premier interpolymère a un degré de ramification inférieur ou égal à 2 méthyles/1000 carbones et ne contient pas de fraction homopolymère mesurable, telle que mesurée par la technique TREF, et où la composition de catalyseur homogène ne contient pas de cocatalyseur d'aluminium ou contient une quantité de cocatalyseur d'aluminium qui donnera un résidu d'aluminium détectable dans le produit, inférieur ou égal à 250 ppm,

(B) provoquer une réaction en mettant en contact de l'éthylène et au moins une autre α -oléfine dans des conditions de polymérisation en solution et à une température de réaction de polymérisation supérieure à celle utilisée dans l'étape (A), en présence d'un catalyseur de Ziegler hétérogène, dans au moins un autre réacteur, de manière à former une solution d'un second interpolymère qui a une distribution structurale large (c'est-à-dire, une distribution structurale telle que la composition contient une fraction homopolymère telle que mesurée par la technique TREF et qui présente de multiples pics de fusion), et une distribution des masses moléculaires large (c'est-à-dire, une distribution des masses moléculaires telle que M_w/M_n est supérieur à 3), dans lequel 10 % en poids ou plus du second interpolymère a un degré de ramification inférieur à 2 méthyles/1000 carbones, et dans lequel 25 % en poids ou moins du second interpolymère a un degré de ramification de 25

méthyles/1000 carbones ou plus, le catalyseur de Ziegler comprenant :

- (i) un élément de support solide dérivé d'un halogénure de magnésium ou de la silice, et
 (ii) un élément de métal de transition représenté par la formule : $\text{TrX}'_{4-q}(\text{OR}^1)_q$, $\text{TrX}'_{4-q}(\text{R}^2)_q$, VOX'_3 ou $\text{VO}(\text{OR}^1)_3$, dans laquelle :

Tr est un métal du groupe IVB, VB, ou VIB,
 q est 0 ou un nombre égal ou inférieur à 4,
 X' est un halogène, et

R¹ est un groupe alkyle, un groupe aryle ou un groupe cycloalkyle ayant 1 à 20 atomes de carbone, et
 R² est un groupe alkyle, un groupe aryle, un groupe aralkyle, ou un groupe aralkyle substitué, et (C)
 combiner la solution du premier interpolymère

avec la solution du second interpolymère de manière à former une solution de polymère contenant la composition d'interpolymères éthylène/α-oléfine, et
 (D) chasser le solvant de la solution de polymère de l'étape (C) et récupérer la composition d'interpolymères éthylène/α-oléfine.

2. Procédé de préparation d'une composition d'interpolymères éthylène/α-oléfine, caractérisé par les étapes consistant à :

(A) polymériser de l'éthylène et au moins une autre α-oléfine dans des conditions de polymérisation en solution, dans au moins un réacteur contenant une composition de catalyseur homogène, de manière à former une solution d'un premier interpolymère ayant une distribution structurale étroite (c'est-à-dire ayant un indice de ramification dans la distribution structurale (CDBI) supérieur à 50 %, l'indice CDBI étant défini comme le pourcentage en poids de molécules du polymère ayant une teneur de comonomère dans les 50 % de la teneur de comonomère totale moyenne telle que mesurée par la technique TREF définie dans la présente), et une distribution des masses moléculaires étroite (c'est-à-dire, une distribution des masses moléculaires telle que M_w/M_n est inférieur à 3), dans lequel 15 % ou moins du premier interpolymère a un degré de ramification inférieur ou égal à 2 méthyles/1000 carbones et ne contient pas de fraction homopolymère mesurable telle que mesurée par la technique TREF, et où la composition de catalyseur homogène ne contient pas de cocatalyseur d'aluminium ou contient une quantité de cocatalyseur d'aluminium qui donnera un résidu d'aluminium détectable dans le produit, inférieur ou égal à 250 ppm,

(B) transférer ensuite séquentiellement la solution d'interpolymère de (A) dans au moins un autre réacteur contenant un catalyseur de Ziegler hétérogène, de l'éthylène et au moins une autre α-oléfine, dans des conditions de polymérisation en solution et à une température de réaction de polymérisation supérieure à celle utilisée dans l'étape (A), de manière à former une solution contenant la composition d'interpolymères éthylène/α-oléfine, le catalyseur de Ziegler comprenant :

- (i) un élément de support solide dérivé d'un halogénure de magnésium ou de la silice, et
 (ii) un élément de métal de transition représenté par la formule : $\text{TrX}'_{4-q}(\text{OR}^1)_q$, $\text{TrX}'_{4-q}(\text{R}^2)_q$, VOX'_3 ou $\text{VO}(\text{OR}^1)_3$, dans laquelle :

Tr est un métal du groupe IVB, VB, ou VIB,
 q est 0 ou un nombre égal ou inférieur à 4,
 X' est un halogène, et

R¹ est un groupe alkyle, un groupe aryle ou un groupe cycloalkyle ayant 1 à 20 atomes de carbone, et
 R² est un groupe alkyle, un groupe aryle, un groupe aralkyle, ou un groupe aralkyle substitué, et

(C) combiner la solution du premier interpolymère avec la solution du second interpolymère de manière à former une solution de polymère contenant la composition d'interpolymères éthylène/α-oléfine, et
 (D) chasser le solvant de la solution de polymère de l'étape (C) et récupérer la composition d'interpolymères éthylène/α-oléfine.

3. Procédé selon l'une des revendications précédentes, dans lequel l'α-oléfine est le 1-octène.

4. Procédé selon l'une des revendications précédentes, dans lequel la composition de catalyseur homogène comprend un complexe métallique de coordination comprenant un métal du groupe 4 de la Classification périodique

des éléments et un fragment à liaison π délocalisée, substitué par un fragment induisant une contrainte, ledit complexe ayant une géométrie contrainte autour de l'atome de métal telle que l'angle au niveau du métal entre le centre de gravité du fragment à liaison π délocalisée substitué et le centre d'au moins un substituant restant est inférieur au même angle dans un complexe similaire contenant un fragment similaire à liaison π , mais dépourvu de substituant induisant une contrainte, et sous réserve, en outre, que pour ces complexes comprenant plus d'un fragment à liaison π délocalisée substitué, un seul de ceux-ci pour chaque atome de métal du complexe soit un fragment cyclique, à liaison π délocalisée substitué.

5. Procédé selon l'une des revendications précédentes, dans lequel la composition de catalyseur homogène comprend, en outre, un cocatalyseur d'activation.

6. Procédé selon l'une des revendications 1 à 5, dans lequel la composition de catalyseur homogène comprend un complexe métallique de coordination correspondant à la formule :

dans laquelle :

M est un métal du groupe 4 de la Classification périodique des éléments ;

Cp* est un groupe cyclopentadiényle ou cyclopentadiényle substitué, lié selon un mode de liaison η^5 à M ;

Z est un fragment comprenant du bore, ou un élément du groupe 14 de la Classification périodique des éléments, et éventuellement, du soufre ou de l'oxygène, ledit fragment ayant jusqu'à 20 atomes de type non-hydrogène, et éventuellement Cp* et Z forment, ensemble, un système à noyau condensé ;

X est, indépendamment, à chaque occurrence, un groupe ligand anionique ayant jusqu'à 30 atomes de type non-hydrogène ;

n est 1 ou 2 ; et

Y est un groupe ligand anionique ou non anionique lié à Z et à M comprenant des atomes d'azote, de phosphore, d'oxygène ou de soufre et ayant jusqu'à 20 atomes de type non-hydrogène, Y et Z formant, éventuellement, ensemble, un système à noyau condensé.

7. Procédé selon l'une des revendications 1 à 5, dans lequel la composition de catalyseur homogène comprend un complexe métallique de coordination correspondant à la formule :

dans laquelle :

R' est, à chaque occurrence, indépendamment choisi dans le groupe composé par l'hydrogène, les groupes alkyle, aryle, et silyle, et leurs combinaisons, ayant jusqu'à 20 atomes de type non-hydrogène ;

X est, à chaque occurrence, indépendamment choisi dans le groupe composé par les groupes hydruure,

halogéno, alkyle, aryle, silyle, aryloxy, alcoxy, amide, siloxy et leurs combinaisons, ayant jusqu'à 20 atomes de type non-hydrogène ;

Y est -O-, -S-, -NR*, -PR*, ou un ligand neutre donneur de deux électrons choisi dans le groupe composé par OR*, SR*, NR*₂ ou PR*₂ ;

M est un métal du groupe 4 de la Classification périodique des éléments ; et

Z est SiR*₂, CR*₂, SiR*₂SiR*₂, CR*₂CR*₂, CR*=CR*, CR*₂SiR*₂, BR* ; où

R* est, à chaque occurrence, indépendamment choisi dans le groupe composé par l'hydrogène, les groupes alkyle, aryle, silyle, alkyle halogéné, aryle halogéné ayant jusqu'à 20 atomes de type non-hydrogène, et leurs mélanges, ou deux groupes R* ou plus provenant de Y, Z, ou Y et Z formant ensemble un système à noyau condensé ;

et n est 1 ou 2.

8. Procédé selon l'une des revendications 1 à 5, dans lequel la composition de catalyseur homogène comprend un composé amidosilane ou amidoalcanediyle correspondant à la formule :

dans laquelle :

M est le titane, le zirconium ou l'hafnium, lié selon un mode de liaison η^5 au groupe cyclopentadiényle ;

R' est, à chaque occurrence, indépendamment choisi dans le groupe composé par l'hydrogène, les groupes alkyle, aryle, et leurs combinaisons, ayant jusqu'à 7 atomes de carbone, ou un groupe silyle ;

E est le silicium ou le carbone ;

X est, à chaque occurrence, indépendamment un groupe hydruure, halogéno, alkyle, aryle, aryloxy ou alcoxy contenant jusqu'à 10 atomes de carbone, ou un groupe silyle ;

m est 1 ou 2 ; et

n est 1 ou 2, quelconque

9. Procédé selon l'une des revendications 1 à 5, dans lequel la composition de catalyseur homogène comprend un catalyseur ionique possédant une structure séparée par des charges limitantes correspondant à la formule :

dans laquelle :

M est un métal du groupe 4 de la Classification périodique des éléments ;

Cp* est un groupe cyclopentadiényle ou cyclopentadiényle substitué lié selon un mode de liaison η^5 à M ;

Z est un fragment comprenant du bore, ou un élément du groupe 14 de la Classification périodique des éléments, et éventuellement, du soufre ou de l'oxygène, ledit fragment ayant jusqu'à 20 atomes de type non-

hydrogène, et éventuellement Cp^* et Z forment, ensemble, un système à noyau condensé ;

X est, indépendamment, à chaque occurrence, un groupe ligand anionique ayant jusqu'à 30 atomes de type non-hydrogène ;

n est 1 ou 2 ; et

5 XA^{n-} est $\text{X}(\text{B}(\text{C}_6\text{F}_5)_3)$.

10. Procédé selon l'une des revendications précédentes, dans lequel la composition de catalyseur homogène a un taux de réactivité inférieur à la moitié de celui du catalyseur hétérogène.

10 11. Composition d'interpolymères éthylène/ α -oléfine qui peut être préparée par le procédé selon l'une des revendications précédentes.
